PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0001 A SCANNING ELECTRON MICROSCOPIC STUDY ON ENDOTHELIAL CELLS AND KUPFFER CELLS IN RAT LIVER SINUSOIDS. (Eng.) Muto, M. (Niigata Univ. Sch. Medicine, Niigata, 951 Japan). *Arch. Histol. Jpn.* 37(5):369-386; 1975.

The results of a scanning electron microscopic (SEM) study on endothelial cells (EC) and Kupffer cells (KC) of liver sinusoids obtained from seven adult white rats and a newborn rat are presented. EC lining the sinusoids showed numerous intracellular openings (large, 1-3 μm and small pores, less than 0.1 μm). Stomata of various sizes were also found between the cells. At the junctional parts of a sinusoid with both a central vein and a portal canal, only the small pores were found. The large pores occurred in the main, intermediate portion of the sinusoid, and the space of Disse was widely continuous through them to the sinusoidal lumen. KC were numerous in the periportal area and showed surface morphology different from EC. Numerous cytoplasmic processes projected from the surface of these cells and were classified into three types: 1) thick, horizontal cytoplasmic processes, 2) microvillous processes, and 3) filo- and lamellipodia. Microvillous processes densely covered the surface of the cell. Filopodia radiated from the margin of the cell and attached to the surface of the adjacent EC. Lamellipodia were observed spreading widely on the surface of the sinusoidal wall. The KC generally were seen on a large endothelial opening anchored to the margin by the filopodia. A filopodial communication between adjacent KC was also demonstrated. KC closely resembled in structure the macrophage cultured *in vitro*. The author suggests that KC are macrophages of the liver that have been incorporated in the formation of the sinusoidal wall.

0002 LYMPHOID CELLS IN CHICKEN INTESTINAL EPITHELIUM. (Eng.) Bjerregaard, P. (Praestevangen 29, DK-3460 Birkerod, Denmark). *Cell Tiss. Res.* 161(4):485-495; 1975.

The intraepithelial lymphoid cells of chicken small intestine were studied by light microscopy (using 1 μ Epon sections) and electron microscopy. There were three cell types: small lymphocytes, large lymphoid cells, and granular cells. These corresponded to the previously described theliolymphocytes and globule leukocytes. The numbers of all cell types increased with age. Correlation was found between the number of small lymphocytes and large lymphoid cells, but not between granular cells and either of the other two. It is proposed that the small intraepithelial lymphocyte is an antigen-sensitive cell. Stimulation by absorbed antigens may either trigger cellular immunity or cause the cell to wander into the lamina propria, where T-B cell cooperation takes place and an immunoglobulin A synthesizing plasma cell is formed.

0003 IDENTIFICATION AND ISOLATION OF BASOLATERAL PLASMA MEMBRANES FROM INTESTINAL EPITHELIAL CELL SHEETS [Abstract]. (Eng.) Lewis, B. A.; Elkin, A.; Michell, R. H.; Coleman, R. (Dept. Biochemistry, Univ. Birmingham, P.O. Box 363, Birmingham B15 2TT, U.K.). *Biochem. Soc. Trans.* 3(5): 754; 1975.

LIBRARY U. OF I.

0C 0 THE ROLE OF THE LATERAL INTERCELLULAR SPACES IN THE CONTROL OF ION PERMEATION ACROSS THE RABBIT GALL BLADDER. (Eng.) Wiedner, G.; Wright, E. M. (Univ. California Medical Center, Los Angeles, CA). *Pfluegers Arch.* 358(1):27-40; 1975.

The role of the lateral spaces in the control of the passive ion permeation across the rabbit gallbladder was studied. Rabbit gallbladders were mounted as flat sheets between two lucite half chambers. Ion selectivity was estimated from NaCl dilution potentials and from CsCl/NaCl bi-ionic potentials. In 11 gallbaldders studied, the average mucosal NaCl dilution potential difference was 9.25 mV, mucosa positive, and the average conductance was 30.8 mOhms/cm^2. When NaCl in the serosal solution was reduced to 74 mM (from 148 mM), there was a rise in the transmural electrical potential, opposite in polarity to the mucosal dilution transmural electrical potential, with a half time for the build-up of 35 sec. The potential difference remained stable as long as the salt gradient was maintained, and it returned to the original baseline value when the initial composition of the serosal solution was restored. When NaCl in the mucosal fluid was replaced with CsCl, the potential difference rose to a peak, and then slowly declined to a steady state value with a half time of 30 sec. Restoring NaCl to the mucosal fluid caused a rapid fall to the transmural potential difference, and an actual overshoot before it returned to baseline value. In eight gallbladders, the peak and steady-state mucosal CsCl/NaCl potential bi-ionic differences were 6.9 and 4.8 mV, resp. Sucrose (300 mM) was added to the mucosal fluid to close the lateral spaces. The resistance increased by a factor of 2.7. NaCl dilution potentials, CsCl/NaCl and LiCl/NaCl bi-ionic potentials were recorded in the presence of sucrose in the mucosal fluid, in the serosal fluid, or in both. The 2:1 NaCl dilution potential difference was 10.9 mV initially and 10.1 mV at the conclusion of the experiments, whereas the CsCl/NaCl bi-ionic potential difference was 8.3 mV (peak) and 5.5 mV (steady state) initially, and 8.3 and 6.1 mV, resp., at the conclusion. Only sucrose in the mucosal solution produced any change in either the NaCl dilution potential difference or the CsCl/NaCl bi-ionic potential difference. Sucrose in the serosal solutions, or in both fluids did not significantly alter either the bi-ionic dilution or potential differences. These data indicate that both the magnitude and selectivity of cation permeation across the rabbit gallbladder epithelium depends upon the status of the lateral intercellular spaces.

0010 ACTIVE TRANSPORT OF IRON TO MUCOSAL SURFACE OF RAT JEJUNUM. (Eng.) Guy, M. J.; Schachter, D. (Columbia Univ. Coll. Physicians Surgeons, New York, NY 10032). *Am. J. Physiol.* 229(3);790-796; 1975.

Steady-state fluxes of divalent Fe across rat intestinal segments were studied *in vitro*. Segments of the distal small intestine transported the mineral against electrochemical potential gradients from the serosal to the mucosal surface. Active transport in the reverse direction was confirmed with segments of proximal duodenum. The distal mechanism was dependent on cellular metabolism and was markedly decreased by metabolic inhibitors or in the absence of a metabolizable hexose. Cycloheximide also blocked the active transport. Perfusion of jejunal and duodenal intestinal loops *in situ* in anesthetized rats provided evidence that endogenous Fe can be transferred to the lumen by a process other than shedding of mucosal cells. It is suggested that such transfer may occur via the active transport mechanism.

0011 ABSORPTION OF DISACCHARIDES IN RATS FED A PROTEIN-DEFICIENT DIET. (Eng.) Leichter, J.; Adams, J. L. (Univ. British Columbia, Vancouver, B.C., Canada V6T 1W5). *Nutr. Rep. Int.* 12(5):311-316; 1975.

Wistar rats (~ 110 g) were maintained on either a 0.5% protein diet or a control diet containing 18% protein for an 8-week period to study the effect of prolonged protein deficiency on intestinal disaccharide absorption. The animals fed the protein-deficient diet lost about 40% of their original body weight, developed bald patches, and became less active. The *in vivo* absorption of radioactive lactose, sucrose, and maltose was higher in the protein-deficient group, the difference being statistically significant only for lactose and maltose absorption ($p < 0.01$). The intestines of the protein-deficient animals were considerably thinner and smaller in diameter compared with the controls, but the total yield of mucosal scrapings per gram of intestine was only slightly greater for the control animals. The results demonstrate that prolonged feeding of protein-deficient diets to growing rats does not interfere with intestinal disaccharide absorption.

0012 STIMULATION OF WATER AND SODIUM SECRETION AND INHIBITION OF GLUCOSE ABSORPTION FROM THE RAT JEJUNUM DURING INTRAARTERIAL INFUSIONS OF PROSTAGLANDINS. (Eng.) Coupar, I. M.; McColl, I. (Dept. Physiology, Monash Univ., Clayton 3186, Australia). *Gut* 16(10):759-765; 1975.

The effect of prostaglandins, isoprenaline, and dibutyryl cyclic AMP (dibut cAMP) on the net transfer of water, Na^+, and glucose absorption were studied in anesthetized male Wistar rats. The lumen of the jejunum was recirculated with a solution of normal saline containing D(+)glucose and 5.6 mM phenosulphonphthalein. The superior mesenteric artery was perfused extracorporeally and drugs were infused into the arterial blood. Prostaglandin E_1 (PGE_1) at infusion rates of 2.5×10^{-9} and 10^{-8} mol/min induced a net secretion of water and Na^+ significantly different from the infused control mean. Both water and Na^+ secretion were dose-related. PGE_1 induced slight but significant inhibition of glucose absorption at 10^{-8} mol/min. This could either be a direct effect or secondary to solvent drag. PGE_2 (2.5×10^{-9} mol/min) and $PGF_{2\alpha}$ (8×10^{-9} mol/min) induced water and Na^+ secretion, and inhibited glucose absorption but not significantly. Isoprenaline (10^{-9} mol/min) and dibut cAMP (8×10^{-9} mol/min) did not alter water, Na^+, or glucose absorption. The authors conclude that the small inhibitory effect of prostaglandins on glucose absorption in the rat jejunum does not appear to be due to alteration in blood glucose concentration or to their vasoactive effects.

0013 A STUDY OF RELATIONS BETWEEN THE ABSORPTION OF AMINO ACIDS, DIPEPTIDES, WATER AND ELECTROLYTES IN THE NORMAL HUMAN JEJUNUM.

(Eng.) Silk, D. B. A.; Fairclough, P. D.; Park, N. J.; Lane, A. E.; Webb, J. P. W.; Clark, M. L.; Dawson, A. M. (St. Bartholomew's Hosp., London EC1A 7BE, England). *Clin. Sci. Mol. Med.* 49(5):401-408; 1975.

A double-lumen perfusion technique was used to study the effect of a wide range of concentrations of glycyl-L-alanine (10-140 mM) and its constituent amino acids on water and electrolyte absorption from iso-osmotic solutions in the upper jejunum of 27 normal human subjects. Ten subjects perfused with sodium chloride (150 mM) served as controls. There was no significant absorption of water and electrolytes from sodium chloride solution (150 mM), but the presence of the dipeptide or its constituent amino acids stimulated water and electrolyte absorption. Water absorption reached a peak at increasing amino acid and dipeptide concentrations and then tailed off. The data suggest that the tailing off is not solely due to the diminished sodium content of the solutions. During perfusion of the dipeptide-sodium chloride and amino acid-sodium chloride solutions, solute and water were absorbed as an iso-osmotic solution. Analysis of the results indicates that this could occur at high dipeptide concentrations only if the majority of the dipeptide enters the cell intact.

0014 STUDIES ON THE NATURE OF COMPLEXES FORMED BY COPPER WITH HUMAN ALIMENTARY SECRETIONS AND THEIR INFLUENCE ON COPPER ABSORPTION IN THE RAT.

(Eng.) Gollan, J. L. (Royal Free Hosp., Pond St., Hampstead, London NW3 2QG, England). *Clin. Sci. Mol. Med.* 49(3):237-245; 1975.

The nature of copper-binding components in human gastrointestinal secretions and their influence on absorption of the metal were studied. Saliva and gastric juice from 10 normal subjects were analyzed as well as saliva from 4 patients and gastric juice from 5 patients with Wilson's disease. Human gastrointestinal secretions formed soluble copper complexes when labeled *in vitro* with ^{64}Cu. Copper-binding substances of low molecular weight were demonstrated in the saliva, gastric juice, and secretin-stimulated duodenal aspirate of normal subjects by dialysis and gel-chromatography studies. The nature of copper complexes formed by secretions obtained from all patients with Wilson's disease was similar to that of complexes formed by secretions of normal subjects. Bile contained a copper-binding fraction of high molecular weight that was more concentrated in gallbladder than hepatic bile. This component (pH 5-8) had a greater binding affinity for copper than the other alimentary secretions or EDTA at a concentration of 10 mM. Absorption of ^{64}Cu from ^{64}Cu-labeled saliva, gastric juice, or L-histidine solution (100 mM) administered intraduodenally into groups of Lister rats was similar to that observed in a control series given [^{64}Cu]cupric acetate in sodium chloride solution. In contrast, the absorption of ^{64}Cu from labeled hepatic and gallbladder bile was significantly reduced. The results suggest that dietary copper forms soluble complexes with the alimentary secretions and that these complexes influence absorption of the metal according to their molecular size. The net uptake of ingested copper from the gut lumen may represent a balance between the influence of dietary chelates, low-molecular-weight ligands in the alimentary secretions, and a macromolecular copper-binding complex of bile.

0015 ISOLATION AND PROPERTIES OF THE MIXED LIPID MICELLES PRESENT IN INTESTINAL CONTENT DURING FAT DIGESTION IN MAN.

(Eng.) Mansbach, C. M.; Cohen, R. S.; Leff, P. B. (Veterans Admin. Hosp., Durham, NC 27710). *J. Clin. Invest.* 56(4):781-791; 1975.

The evaluation of physicochemical characteristics of human fat digestion was facilitated by a method that allowed characterization of the bile acid-lipid mixed micelles of the aqueous phase of postprandial duodenal fluid. Duodenal fluid was collected from six subjects who had eaten a 36-g fat breakfast for two 90-min periods and for 45 min after i.v. cholecystokinin (75 Ivy U) infusion. The samples were ultracentrifuged at 15,400,000 x *g*-min, the aqueous phase was isolated and passed through a 220-nm filter. The mixed micelles were concentrated by an ultrafiltration procedure using a 1.5-nm filter. The 1.5-nm retentate was eluted from Sepharose 6B columns with 1.5-nm filtrate for both pre-equilibration fluid and eluent. The 1.5-nm filtrate approximated the monomer concentrations. Each sample was assayed for bile acid, fatty acid, lecithin, lysolecithin, protein, cholesterol, and counterions (pH, Na^+, K^+, Ca^{2+}). Constituents were concentrated only on the 1.5-nm filter. On gel permeation chromatography, coincident peaks were observed for bile acid, fatty acid, lysolecithin, and cholesterol, and were eluted with a *Kav* range of 0.50-0.68 (corresponding to a Stokes radius of 2.3-3.5 nm). An average density of 1.25 and coincident peaks of bile acid and fatty acid were found for the mixed micelles on sucrose density gradients. The regression lines of micellar fatty acid, lysolecithin, and cholesterol versus bile acid gave a stoichiometry of 1.4 M fatty acid, 0.15 M lysolecithin, and 0.06 M cholesterol for each mole of bile acid. Mixed micelles were homogeneous in composition. These results provide direct evidence for the existence of the postprandial mixed micelle.

0016 THE EFFECT OF FRUSEMIDE ON WATER AND ELECTROLYTE ABSORPTION FROM THE HUMAN JEJUNUM.

(Eng.) MacKenzie, J. F.; Cochran, K. M.; Russell, R. I. (Royal Infirmary, Glasgow G4 OSF, Scotland). *Clin. Sci. Mol. Med.* 49(5):519-521; 1975.

The effect of frusemide (4-chloro-*N*-furfuryl-5-sulamoylanthranilic acid) on water and electrolyte absorption in the jejunum of 12 normal subjects and its relation to diarrhea were studied. Using a double-lumen perfusion system with proximal occluding balloons, 120 nM (40 mg, i.v.) frusemide significantly reduced the absorption of water and electrolytes from the jejunum. Net secretion of water and electrolytes occurred in some subjects. No significant change in water and electrolyte absorption was observed with 60 nM (20 mg) of frusemide. The results demonstrate an alteration in transport mechanisms in the human jejunum and may explain the diarrhea that occurs in some patients when given high doses of frusemide.

0017 THE EFFECTS OF UNDERNUTRITION AND ITS RELIEF ON INTESTINAL CALCIUM TRANSPORT IN THE RAT. (Eng.) Adams, P. H.; Hill, L. F.; Wain, D.; Taylor, C. (Royal Infirmary, Manchester, England). *Calcif. Tissue Res.* 16(4):293-304; 1974.

Active transport of calcium across the duodenum was measured *in vitro* in 36 normal Wistar rats and in rats during undernutrition and subsequent rehabilitation. In rats growing normally, duodenal calcium transport was an inverse function of age and the length and mineral concentration of the femur. Duodenal calcium transport was reduced during undernutrition (31 rats) and was stimulated when the undernutrition was relieved (21 rats). Calcium transport was not related to age or to the size and composition of the femur during undernutrition and rehabilitation. Calcium transport across the duodenum was a direct function of rate of growth. This finding supports the view that calcium absorption is related to the needs of the organism at the time. Duodenal calcium transport, which was reduced in slowly growing rats, both undernourished and normal, could be stimulated with small amounts of 1,25-dihydroxycholecalciferol (1,25-DHCC, 5 or 25 ng, i.v.) but not with large amounts of cholecalciferol (5.0 μg, i.v.) or 25-hydroxycholecalciferol (2.5 μg, i.v.). These findings may suggest that the growth rate of the body has a bearing on the production of and/or metabolism of 1,25-DHCC.

0018 CHLORIDE MOVEMENT ACROSS MONOLAYERS OF ENRICHED POPULATIONS OF ISOLATED EPITHELIAL CELLS FROM THE MOUSE GASTRIC MUCOSA. (Eng.) Munro, D. R.; Romrell, L. J.; Coppe, M. R.; Ito, S. (Harvard Medical Sch., Boston, MA 02115). *Exp. Cell Res.* 96(1):69-76; 1975.

The abilities of monolayers of mouse epithelial gastric parietal cells and other gastric epithelial cell types to transport chloride were tested with respect to the direction of the current flow used to polarize the cells. Enriched, viable populations of large parietal cells were separated from the smaller cells (surface mucous, mucous neck, chief, and endocrine cells) of the gastric mucosa of five CD-1 mice by pronase digestion and velocity sedimentation. These enriched cell populations were allowed to form a layer on Teflon Millipore filters mounted in lucite chambers. The interface formed by the Millipore filters separated compartments designated "luminal" and "interstitial." The luminal and interstitial phases each contained 5 ml of the same balanced salt solution. The cell populations were polarized by applying a potential difference of approximately 50 mV across the interface while the cells were forming a layer on the filter. Analysis of the luminal and interstitial solutions after 2 hr demonstrated that polarized parietal cell monolayers transported chloride toward the cathode, whereas the similarly polarized small cell monolayers always moved chloride toward the anode. When similar populations of cells were not polarized with an external potential difference, any net chloride movement that occurred was random. The results demonstrate the physiologic polarization of monolayers of parietal mouse gastric mucosal cells with respect to the direction of current flow and their ability to transport chloride.

0019 EFFECTS OF THEOPHYLLINE ON Na AND ALANINE TRANSPORT ACROSS ISOLATED RABBIT ILEUM. (Eng.) Fromm, D.; Field, M. (Harvard Medical Sch., Boston, MA 02215). *Am. J. Physiol.* 229(3):683-688; 1975.

The possibility that in the presence of secretion both unidirectional sodium fluxes contain large nondiffusional components was studied in isolated male New Zealand rabbit ileum using theophylline (10 mM). Addition of theophylline to the ileal mucosa caused a persistent increase in short-circuit current (SCC) and a persistent decrease in DC conductance. Under short-circuit condition, net Na flux (J^{Na}_{net}) was reversed by theophylline from absorption to secretion (-0.6 μEq/hr cm^2) and was due to a decrease in unidirectional mucosal-to-serosal flux (J^{Na}_{ms}). Addition of L-alanine (5 mM) to theophylline-treated mucosa increased SCC, J^{Na}_{net}, and J^{Na}_{ms}. Theophylline reduced J^{Ala}_{net} by 25%. Na flux ratios, in the presence of theophylline at +26 and -11 mV (mucosal reference), differed from flux ratios expected for a diffusional process by less than 8%. In contrast, Na flux ratios, determined in the absence of theophylline and the presence of glucose (3 mM) at +26 and 0 mV, differed from diffusional ratios by 35%. The results are consistent with the hypothesis that theophylline inhibits active Na absorption, but do not conclusively demonstrate the diffusional nature of unidirectional Na fluxes in the presence of theophylline.

0038 DISTRIBUTIONS OF SPIKE BURSTS IN CAT DUODENUM. (Eng.) Sancholuz, A. G.; Croley, T. E., II; Glover, J. R.; Macagno, E. O.; Christensen, J. (Dept. Internal Medicine, Univ. Iowa, Iowa City, IA 52242). *Am. J. Physiol.* 229 (4):925-929; 1975.

The histograms of spike bursts over short distances were examined in the isolated duodenum of 16 cats *in vitro* to estimate the dimensions and configurations of single ring contractions. Multiple electrodes were arranged circumferentially and longitudinally. At a single cross section of the duodenum, spike bursts occurred simultaneously in any single slow-wave cycle, but all eight monitored sites in the circumference participated simultaneously only in about 25% of the spike-burst cycles. Wide variations in the incidence of spike bursts at different locations in a planar cross section were also evident. In a longitudinal section, net level of activity over short distances varied widely. Spike bursts were out of phase in the longitudinal axis, appearing to spread caudad; 80% of spike-burst groups involved less than an average of 5.5 consecutive electrode sites (spaced at 5-mm intervals). The sequential appearance in time and the correlation of spike bursts with ring contractions of the circular muscle suggests that such contractions must always be peristaltic. An estimated 80% of such contractions sweep less than about 3 cm. The demonstration of a great degree of variation in activity over very short distances implies that records of spike bursts from a single electrode do not accurately reflect activity beyond that one point site.

0039 PHASE LOCK OF ELECTRICAL SLOW WAVES AND SPIKE BURSTS IN CAT DUODENUM. (Eng.) Sancholuz, A. G.; Croley, T. E., II; Christensen, J.; Macagno, E. O.; Glover, J. R. (Univ. Iowa Coll. Medicine and Engineering, Iowa City, IA 52242). *Am. J. Physiol.* 229(3):608-612; 1975.

The phase relation between slow waves and spike bursts was studied *in vitro* in the duodenums of 11 healthy cats. Electrodes were arranged radially about 10-cm duodenal segments excised 1 cm below the pylorus to the ligament of Treitz. Records were read for T_1, the time between the slow-wave "valley" and the first spike, and T_2, the time between successive valleys. The distributions of the ratio T_1/T_2 showed very small differences, not uniquely attributable to radial electrode position. The distribution of T_1/T_2 indicated that spike bursts began 58.8% of the way through a slow-wave cycle, measured from the valley. Also, electrodes were arranged longitudinally and records were read to determine ΔSW, the slow-wave delay time between adjacent electrode positions, and ΔS, the spike burst delay time between adjacent electrode positions. The correlation of ΔS and ΔSW suggested a linear relation, and a regression resulted in a good linear description. These results are consistent with an assumed phase lock of spike bursts to slow waves.

0040 ELECTRICAL ACTIVITY OF SMALL INTESTINAL SMOOTH MUSCLE AND ITS TEMPERATURE DEPENDENCE. (Eng.) El-Sharkawy, T. Y.; Daniel, E. E. (Mayo Graduate Sch. Medicine, Mayo Foundation, Rochester, MN 55901). *Am. J. Physiol.* 229(5):1268-1276; 1975.

The spontaneous electrical activity of rabbit jejunal longitudinal muscle strips with reference to the configuration of the control potential, the effects of temperature, and their implications regarding the ionic basis and triggering mechanisms of the intestinal control potential were described. The spontaneous electrical activity consisted of two main components: the control activity and the response activity. The control potentials (CP), or slow waves, consisted of repetitive 18 mV depolarizations that lasted 2 sec at 37 C, had a frequency of 18/min, and arose from a membrane potential of -55 mV. In some cells, periods between CP's exhibited "diastolic" progressive depolarizations (intercontrol-potential depolarization), which may be the trigger of the CP in driving cells. While CP was usually monophasic, some cells persistently exhibited a notch early in the plateau phase. It is suggested that CP consists of two components, an "initial depolarization" and a "secondary depolarization," which are usually fused together to give a monophasic potential. Cooling reduced CP frequency and prolonged its duration and caused more cells to show notching. While amplitude and rate of CP initial depolarization had low Q_{10}'s, duration and rates of onset and offset of the secondary depolarization had higher Q_{10}'s. Thus, the process responsible for secondary depolarization is more sensitive to temperature than that underlying initial depolarization of the CP.

0041 ELECTROGENIC SODIUM PUMPING IN RABBIT SMALL INTESTINAL SMOOTH MUSCLE. (Eng.) El-Sharkawy, T. Y.; Daniel, E. E. (Mayo Graduate Sch. Medicine, Mayo Foundation, Rochester, MN 55901). *Am. J. Physiol.* 229(5):1277-1286; 1975.

The electrogenicity of the electrogenic sodium pump was investigated in rabbit jejunal smooth muscle to determine whether this pump is the ionic mechanism underlying the intestinal control potential (slow wave). Potassium admission to Na-rich tissues caused a large increase in membrane potential that decreased after 10-20 min toward values comparable with those of normal tissues. This hyperpolarization far exceeded the K equilibrium potential and could be prevented by cooling or by ouabain treatment (1 x 10^{-5} M). No hyperpolarization occurred upon K admission to Li-rich tissues in the absence of Na. Thus, the pump in this tissue can operate electrogenically. Goldman's equation was modified to account for the pump's contribution to the membrane potential. Using this equation, the calculated contribution of the pump under normal "steady-state" conditions was unlikely to exceed a few millivolts. It is concluded that although the pump in this tissue can be electrogenic, its contribution may be smaller than that required if the intestinal control potential resulted from rhythmic turning off and on of the electrogenic Na pump.

0042 IONIC MECHANISMS OF INTESTINAL ELECTRICAL CONTROL ACTIVITY. (Eng.) El-Sharkawy, T. Y.; Daniel, E. E. (Mayo Graduate Sch. Medicine, Mayo Foundation, Rochester, MN 55901). *Am. J. Physiol.* 229(5):1287-1298; 1975.

The effects of inhibition and stimulation of the electrogenic sodium pump and of altering the ionic environment on the electrical control activity (ECA) were studied in rabbit jejunal smooth muscle. Pump inhibition abolished the ECA at a time when the membrane potential was more negative than the peak depolarization of the control potential (CP). Pump stimulation hyperpolarized the membrane and CP's appeared. Their amplitude was initially small and progressively increased as the hyperpolarization subsided. Lowering external Na to 20 mM or Ca withdrawal, but not addition of verapamil (5×10^{-6} M), reversibly abolished the ECA. Chloride replacement by propionate, isethionate, or benzene-sulphonate caused a transient augmentation, followed by suppression of the secondary depolarization of the CP's and decreased their frequency. The initial depolarization of the CP was little affected. Nitrate substitution increased CP frequency and spiking activity but had no observable effects on the CP configuration. These results suggest that the intestinal control potential may result from conductance changes initially to Na and later to Cl rather than from an oscillatory electrogenic pump.

0043 THE EFFECT OF METOCLOPRAMIDE ON INHIBITION INDUCED BY PURINE NUCLEOTIDES, NORADRENALINE, AND THEOPHYLLINE ETHYLENEDIAMINE ON INTESTINAL MUSCLE AND ON PERISTALSIS IN VITRO. (Eng.) Okwuasaba, F. K.; Hamilton, J. T. (Dept. Pharmacology, Univ. Western Ontario, London, Ontario N6A 5C1, Canada). *Can. J. Physiol. Pharmacol.* 53(5):972-977; 1975.

The interactions between metoclopramide [*N*-(diethylaminoethyl)-2-methoxy-4-amino-5-chlorobenzamide, Mcp] and noradrenalin, theophylline ethylenediamine, ATP, ADP, and adenosine were studied in isolated intestinal preparations and on peristaltic activity in the guinea pig ileum to determine if Mcp effects the action of purine nucleotides. Mcp (0.1 and 1.0 μM) partially and significantly reduced the relaxations induced by ATP, ADP, and adenosine. Mcp was without effect on theophylline ethylenediamine, while it significantly potentiated noradrenalin on the atropine-pretreated (0.1 μM) tenia coli, rabbit ileum, and rat duodenum. Mcp (1.0 μM) decreased the inhibitory effects of ATP, ADP, and adenosine on peristalsis induced in the isolated guinea pig ileum by a constant increase in intraluminal pressure. It did not affect inhibition due to theophylline ethylenediamine, but potentiated inhibition of peristalsis due to noradrenalin. It is proposed that this effect of Mcp may be a specific antagonistic action on receptors sensitive to the putative purinergic transmitters, ATP and ADP, and may be partly responsible for its observed action on peristalsis.

0044 ACTION OF BOMBESIN ON THE MOTILITY OF THE STOMACH. (Eng.) Bertaccini, G.; Impicciatore, M. (Universita di Parma, Istituto di Farmacologia, Ospedale Maggiore, I-43100 Parma, Italy). *Naunyn Schmiedebergs Arch. Pharmacol.* 289 (2):149-156; 1975.

The pharmacological activity of bombesin on the stomach of the rat, dog, and man was studied under different experimental conditions. Bombesin stimulated whole-stomach contractions in female Wistar rats at all times. Blocking of the duodenal effluent during exclusion of the pyloric sphincter was preceded by an intermediate increase in the frequency of the drops of effluent, resulting from stomach wall contraction. Doses of 1-5 ng/kg instilled *in situ* in the rat caused partial duodenal effluent restriction while 100 ng/kg caused a block lasting about 1 hr. While good dose-activity response was seen in some rats, tachyphylaxis was observed in others. The C-terminal nonapeptide of bombesin had a similar effect to that of the parent compound. Cerulein exerted an effect only at the gastroduodenal junction. Heidenhain pouches in mongrel dogs were stimulated only with large doses of bombesin (0.1-0.5 μg/kg); the innervated portion of the stomach was virtually insensitive to doses up to 3 μg/kg. Cerulein, however, produced a constant increase in tone and amplitude with doses from 0.05 to 0.2 μg/kg. Tachyphylaxis was present in all experiments, and the behavior of the C-terminal nonapeptide was identical to that of bombesin. In human isolated stomach muscle strips, bombesin (3-30 ng/ml of bath) stimulated both circular and longitudinal muscle and a good dose/effect relation was found. Infusion of bombesin (10-20 ng/kg/min) during radiological examination produced an increase in tone in the antrum and a simultaneous decrease in tone and motility in the body and fundus. The authors suggest that bombesin has a direct effect on the *in situ* rat stomach and on the isolated preparations, while it has an indirect effect on *in situ* innervated preparations of the dog and man.

0045 INTERACTION BETWEEN OCTAPEPTIDE-CHOLECYSTOKININ, GASTRIN, AND SECRETIN ON CAT GALLBLADDER IN VITRO. (Eng.) Chowdhury, J. R.; Berkowitz, J. M.; Praissman, M.; Fara, J. W. (Albert Einstein Coll. Medicine, Bronx, NY). *Am. J. Physiol.* 229(5):1311-1315; 1975.

The effects of synthetic octapeptide of cholecystokinin (OP-CCK), synthetic human gastrin I, and pure natural and synthetic secretin on isometric tension development in strips of cat gallbladder were studied. Effective molar concentrations were 2.2×10^{-10} to 5.3×10^{-9} for OP-CCK and 1.13×10^{-7} to 1.8×10^{-6} for gastrin. The maximal response to gastrin averaged 66% of the maximal response to OP-CCK, and the effects were not blocked by atropine. Secretin was weakly stimulatory or ineffective by itself. Prior addition of submaximal doses of gastrin shifted the dose-response curve of OP-CCK to the right, but neither the slope nor the calculated maximal response (CMR) was significantly changed, suggesting that gastrin and OP-CCK compete for a common receptor on cat gallbladder. A background dose of secretin shifted the dose-response curves for both OP-CCK and gastrin to the left and increased the slopes significantly with increase in the respective CMR. The combined action of OP-CCK (or gastrin) and secretin are supra-additive. These experiments suggest that OP-CCK and gastrin act at a common receptor site that is different from the secretin-receptor site.

0046 MECHANISM OF ACTION OF PENTAGASTRIN AND ACETYLCHOLINE ON THE LONGITUDINAL MUSCLE OF THE CANINE ANTRUM.

(Eng.) Szurszewski, J. H. (Mayo Medical Sch., Rochester, MN 55901). *J. Physiol. (Lond.)* 252(2):335-361; 1975.

Electrical and mechanical activities of the longitudinal muscle of the dog antrum were recorded with the double sucrose-gap technique. The muscle exhibited spontaneous action potentials that consisted of a spike-like potential (amplitude averaged 23 mV) that, after a brief and partial repolarization, was followed by a negative-going, plateau-type potential (amplitude averaged 17 mV). In 97% of the muscle preparations, no tension changes were produced by spontaneous action potentials. Tetrodotoxin (10^{-5} M), atropine (10^{-5} M), alpha- and beta-adrenoceptor antagonists (phentolamine, 10^{-6} M; phenoxybenzamine, 10^{-6} M; and propranolol, 10^{-6} M, resp.), and H_1 and H_2 receptor blocking agents (mepyramine and metiamide, 10^{-6} M, resp.) had no effect on the action potential. It is concluded that the action potential was myogenic in origin. Steady depolarizing current increased, whereas hyperpolarizing current decreased, the frequency of the action potential. In twelve muscle strips in which length-tension relations were studied, the average resting tension at L_0 was 570 mg. The active force of isometric contraction produced by acetylcholine increased with strip length up to a maximum, then decreased with further increases in length. On smooth muscle, pentagastrin (2×10^{-14} to 10^{-11} M) increased the frequency of the action potential in a dose-dependent fashion. Pentagastrin also released acetylcholine from intramural cholinergic nerves. Acetylcholine produced phasic contractions that were associated with action potentials, and as long as it was present in the bathing solution, it increased the amplitude and duration of the action potential. When acetylcholine and pentagastrin were present together in the solution, phasic contractions occurred at the frequency of the action potential. The results indicate that in the longitudinal muscle of the dog antrum, gastrin increases the occurrence of gastric contraction by releasing acetylcholine from intramural cholinergic nerves and increases the incidence of contraction by acting on smooth muscle to increase and regularize the frequency of the action potential.

0047 EFFECT OF PROSTAGLANDIN-E_2 ON MYOELECTRICAL AND MECHANICAL ACTIVITY OF TOTALLY ISOLATED, EX-VIVO-PERFUSED, CANINE STOMACH.

(Eng.) Kowalewski, K.; Kolodej, A. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton T6G 2H7, Canada). *Pharmacology* 13(4):325-339; 1975.

The effects of prostaglandin-E_2 (PGE_2) on myoelectrical and mechanical activity of the isolated, homologous perfused canine stomach were studied. Electrical control activity (ECA) was first recorded for 20-30 min prior to administration of the stimulants. A flash injection of 25 µg of PGE_2 into the gastric artery led to production of premature control potentials, uncoupling of ECA, and to a weak mechanical response of short duration. After vagal stimulation of the nerve of Latarjet, or after flash injection of pentagastrin (2.5 µg) or methacholine (5 µg), similar changes in ECA were observed, but mechanical response corresponding to antral contractions was very pronounced. Prolonged infusion of PGE (500 µg/hr) induced a marked increase of ECA frequency. A similar effect on ECA frequency was observed during infusion of pentagastrin (32 µg/hr). Infusion of PGE_2 abolished mechanical response but infusion of pentagastrin stimulated this response. Effects of a flash injection of PGE_2 on electrical activity were reduced by hexamethonium and abolished by tetrodotoxin and atropine. The action of the blocking agents on PGE_2-induced changes in ECA was similar to the action of these blockers on gastric myoelectrical activity, stimulated vagally or by injection of pentagastrin and methacholine. Infusion of PGE_2 induced a marked reduction in gastric peripheral vascular resistance, but no time-correlation between hemodynamic effects of PGE_2 and its action of gastric musculature was noted. The results demonstrate that PGE_2 acts essentially on gastric ECA, but does not induce electrical response activity. This may be explained by the stimulation of longitudinal muscles and the inhibition of circular muscles by PGE_2.

0048 AN ANALYSIS OF THE MECHANICAL RESPONSES OF THE ISOLATED ILEUM TO SINGLE TRANSMURAL STIMULATION AND TO DRUGS.

(Eng.) Ohkawa, H. (Yamaguchi Univ. Sch. Medicine, Ube, Japan) *Bull. Yamaguchi Med. Sch.* 21(1-4):31-45; 1974.

The mechanical responses of the isolated ileum of the guinea pig to single transmural stimulation of the intrinsic nerves and to drugs were studied. Excitatory dominant and inhibitory dominant types of responses were observed. Rebound-contraction produced by single transmural stimulation was also demonstrated. Atropine (10^{-6} g/ml) or hyoscine (10^{-5} g/ml) abolished the primary contraction and produced the relaxation type response. The initial relaxation was dependent on the tension level at which the single transmural stimulation was given. Tetrodoxin, (1.6×10^{-7}g/ml) but not hexamethonium (0.8-1.6×10^{-6} g/ml), inhibited the primary contraction, the initial relaxation, and the rebound-contraction by blocking the activity of the intrinsic nerves. Phenoxybenzamine (10^{-6} g/ml) partly inhibited the initial relaxation, and guanethidine (10^{-5} g/ml) had no effect on it. ATP and ADP potentiated the initial relaxation, suggesting the existence of nonadrenergic inhibitory neurons in the guinea pig ileum. This result suuports the possibility that ATP or a related compound is a transmitter substance released by nonadrenergic inhibitory nerves. The authors conclude that three types of intrinsic nerves are included in the wall of the guinea pig ileum. Rebound-contraction does not appear bo be a nerve-mediated phenomenon. The process of the rebound-contraction may be due to intrinsic mechanism in smooth muscle cells due to the preceding hyperpolarization.

SECRETION AND METABOLISM

0059 STIMULATION OF SECRETION OF GASTRIC INHIBITORY POLYPEPTIDE AND INSULIN BY INTRADUODENAL AMINO ACID PERFUSION. (Eng.) Thomas, F. B.; Mazzaferri, E. L.; Crockett, S. E.; Mekhjian, H. S.; Gruemer, H. D.; Cataland, S. (Ohio State Univ. Hosp., Room N-937, 410 West 10th Ave., Columbus, OH 43210). *Gastroenterology* 70(4):523-527; 1976.

The effect of intraduodenal or i.v. administration of a 30-g mixed amino acid solution on serum gastric inhibitory polypeptide (GIP), α-amino nitrogen (AAN), glucose, and insulin concentrations was studied in 10 normal subjects (6 men and 4 women). A second experiment with 12 normal subjects was conducted to determine the effect of osmolality changes of the duodenal perfusate on serum GIP levels. Initially, an intraduodenal amino acid perfusion (15 ml/min x 60 min) was performed in each subject and was followed in 1-2 weeks by an i.v. infusion. Peak AAN concentrations occurred at 60 min after both routes of administration, but were greater with i.v. infusion, 145 μg/ml versus 89 μg/ml. Although serum AAN levels were significantly lower after intraduodenal administration, incremental insulin concentrations were greater after intraduodenal perfusion, 77.3 μU/ml versus 43.1 μU/ml. Total integrated insulin secretion was also

LIBRARY U. OF I.

greater after intraduodenal amino acids, 5000 versus 2400 μU-min/ml. With i.v. amino acid infusion, serum GIP concentrations remained below the assay detection limit. After intraduodenal perfusion, a mean maximum GIP increment of 468 pg/ml occurred at 15 min. In all subjects peak GIP concentrations occurred at 15 min and preceded the maximum insulin rise by 15-30 min. Total integrated GIP secretion was significantly greater after intraduodenal amino acid perfusion, 13,000 pg-min/ml versus no measurable response with i.v. infusion. In the second study, no significant changes in serum GIP concentrations occurred after intraduodenal perfusion of 0.45% saline, 0.9% saline, or 10% mannitol. The results demonstrate that intraduodenal amino acid administration stimulates the secretion of GIP in association with an augmentation of insulin secretion. The authors suggest that endogenously released GIP may be important in the enteric mediated release of insulin.

0060 POTENCY AND SELECTIVITY OF METHYL ANALOGUES OF PROSTAGLANDIN E_2 ON RAT GASTROINTESTINAL FUNCTION. (Eng.) Main, I. H. M.; Whittle, B. J. R. (Sch. Pharmacy, Univ. London, 29/39 Brunswick Square, London, WC1N 1 AX, England). *Br. J. Pharmacol.* 54(3):309-317; 1975.

The potency and selectivity of action of prostaglandin E_2 and its [15S]- or [15R]-15-methyl and 16,16-dimethyl analogues on gastrointestinal function were studied in the rat. The [15S]-15-methyl and 16,16-dimethyl analogues were 40 times as active as prostaglandin E_2 in inhibiting pentagastrin-stimulated acid secretion on i.v. administration to the anesthetized rat, and 100 times as active on s.c. injection to the chronic fistula rat. In antisecretoy doses, the analogues, like prostaglandin E_2, caused bile reflux and, in higher doses, profuse diarrhea. The [15S]-15-methyl and 16,16-dimethyl analogues were at least 30 times as active as prostaglandin E_2 in causing changes in intestinal intraluminal pressure *in vivo*, but were equipotent on isolated smooth muscle. In equivalent antisecretory doses, the methyl analogues had little effect on systemic arterial blood pressure and resting mucosal blood flow compared with prostaglandin E_2. The [15R]-methyl epimer administered parenterally had little effect on gastrointestinal function, but brief acid incubation greatly increased its activity. The results indicate that in the rat the greatly increased potency of 16,16-dimethyl and [15S]-15-methyl prostaglandin E_2 in inhibiting acid secretion is accompanied by little or no increase in selectivity with respect to intestinal motility.

SECRETION AND METABOLISM

Stomach

0068 Ba^{++} AS A GASTRIC STIMULANT: RELEASE OF HISTAMINE. (Eng.) Rangachari, P. K. (Univ. California Sch. Medicine, San Francisco, CA 94143). *Am. J. Physiol.* 229(3):627-631; 1975.

Ba^{2+} was studied to determine whether it induces acid secretion in the isolated frog stomach by releasing an endogenous substance, and whether its effects on transmucosal resistance can be dissociated from the effect on acid secretion. Ba^{2+} (2mM) added to the serosal solution bathing the resting stomach increased transmucosal resistance and induced acid secretion. The increase in acid secretion was associated with an increased leak of histamine from the mucosa into the serosal solution. Pretreatment with burimamide inhibited the secretory response. After a pulse treatment with 2 mM Ba^{2+} for 5 min, the effects on resistance were transient, but the effects on acid secretion were sustained. A pulse treatment with histamine also led to a sustained increase in acid secretion, and this increase was blocked by burimamide. It is concluded that Ba^{2+} releases histamine, which then stimulates acid secretion.

0069 ULTRASTRUCTURAL AND PHYSIOLOGICAL CHANGES IN PIGLET OXYNTIC CELLS DURING HISTAMINE STIMULATION AND METABOLIC INHIBITION. (Eng.) Forte, T. M.; Machen, T. E.; Forte, J. G. (Donner Lab., Univ. California, Berkely, CA 94720). *Gastroenterology* 69(6):1208-1222; 1975.

Neonatal pig mucosa was studied in order to correlate electrophysiological and secretory parameters with ultrastructural changes in membrane components of oxyntic cells during conditions of rest, histamine-stimulation (5 x 10^{-5} M), and metabolic inhibition effected by anaerobiosis. The nonstimulated tissue had a transmucosal resistance of about 130Ω x cm^2, while the oxyntic cells were characterized by numerous cytoplasmic tubulovesicles and short microvilli extending into patent glandular and canalicular lumina. Upon histamine stimulation, the average rate of H$^+$ secretion was 8.1 μEq/cm^2/hr, and the resistance decreased to 77Ω x cm^2. The changes were coupled with an immense elaboration of the oxyntic cell apical and canalicular surfaces with a concomitant decrease of tubulovesicles. The observed decrease in resistance was correlated to large increases in secretory membrane area. Anoxia inhibited H$^+$ secretion while resistance increased to 211Ω x cm^2. Anoxic oxyntic cells were characterized by swollen mitochondria and occlusion of the lateral intercellular space and basal infoldings. Little change in the configuration of the secretory surfaces was noted, suggesting that restriction of lateral and basal membranes might be responsible for the observed resistance increase. The results confirm previous studies that indicate that profound membrane structural alterations are associated with the secretory and metabolic state of gastric oxyntic cells. The authors propose an electrical analogue of gastric mucosa on the basis of these observations.

0070 DOES PENTAGASTRIN SUPPRESS SECRETIN INDUCED PEPSIN SECRETION IN HEIDENHAIN POUCH DOGS? (Eng.) Magee, D. F.; Nakajima, S. (Creighton Univ. Sch. Medicine, 2500 California St., Omaha, NB 68178). *Experientia* 31(7):821-822; 1975.

Experiments were performed to determine whether pentagastrin could diminish the stimulatory action of secretin or methacholine on Heidenhain pouch pepsin in dogs. Secretin (1 U/min infusion)-stimulated pepsin secretion from Heidenhain pouches was significantly depressed by concomitant pentagastrin (0.5, 1, or 2 μg/min, i.v.) in six dogs. Pentagastrin by itself was without effect on pouch pepsin. Methacholine, (0.5, 1, or 2 U secretin/min superimposed over 2 μg/min methacholine) in 10 dogs, did not antagonize secretin-stimulated pouch pepsin. The authors conclude that in Heidenhain pouches, pentagastrin antagonizes secretin-stimulated pepsin, while secretin and methacholine do not antagonize one another.

0071 GASTRIN RESPONSE TO MEALS OF DIFFERENT COMPOSITION IN NORMAL SUBJECTS. (Eng.) Blair, E. L.; Greenwell, J. R.; Grund, E. R.; Reed, J. D.; Sanders, D.J. (Dept. Physiology, The Univ., Newcastle upon Tyne, England). *Gut* 16(10):766-773, 1975.

Serum gastrin responses and the integrated gastrin responses to eating 3 meals of very different composition were studied in 11 male volunteers on a number of days. Two meals, a milk meal of 500 ml and a breakfast of eggs, toast, butter, marmalade, fruit juice, and coffee, were eaten at breakfast time. The serum gastrin responses to these meals were compared with the concentrations observed when the subjects fasted over the same time of day. A steak meal was eaten at lunch time. There were no significant differences between the mean serum gastrin concentrations to the three meals, but each meal produced a significant increase in serum gastrin above fasting levels. When the prefeeding gastrin concentration was subtracted from the gastrin responses, the integrated responses to the steak meal were greater than those to either of the breakfast meals. Considerable variability in response to any one meal was observed within the group of subjects, but those subjects who produced high serum gastrin concentrations to one meal did so to the others. Conversely, a low response to one meal was reflected in low responses to the other two meals. Fasting serum gastrin concentration was correlated with the age of the subject. Repeatability of the response to one meal was tested in two subjects who ate the same meal on four separate occasions showing their responses to be repeatable. It is concluded that the total gastrin concentrations and total integrated responses following each of the three meals were very similar despite the differences in size and composition of the meals, possibly indicating the existence of normal effective feedback mechanism controlling gastrin response.

SECRETION AND METABOLISM

Pancreas

0086 INFLUENCE OF A SYNTHETIC PROSTAGLANDIN ANALOG ON PANCREATIC SECRETION. (Eng.) Rosenberg, V.; Biezunski, D.; Gonda, M.; Dreiling, D. A.; Rudick, J.; Robert, A. (Mount Sinai Sch. Medicine, 5th Ave. and 100th St., New York, NY 10029). *Surgery* 79(5):509-514; 1976.

The effects of a synthetic prostaglandin analog, 16,16-dimethyl prostaglandin E_2, methyl ester (16-diMe-PGE$_2$), on pancreatic secretion were evaluated in seven mongrel dogs with chronic duodenal fistulas. Graded doses of 16-diMe-PGE$_2$ were administered i.v. (0.1, 0.3, 0.5, and 1.0 μg/kg), intraduodenally, or intragastrically (15, 30, 50, 100 μg/kg) with the pancreas in the resting state or in response to secretin and secretin with cholecystokinin-pancreozymin. Profound and prolonged inhibition of volume and bicarbonate concentration of secretion occurred in the resting and stimulated gland. ED_{50} was 0.31 μg/kg i.v. (1/75 the ED_{50} for PGE_1) and 25 μg/kg intraduodenally. As with PGE_1, stimulation of enzymes occurred, even with doses that were subthreshold for inhibition of volume and HCO_3. Like PGE_1, 16-diMe-PGE_2 had a dual action on the intact canine pancreas (stimulation of enzymes and inhibition of volume and electrolytes), but was much more potent, had a prolonged action, and was active intraduodenally and intragastrically. Nonsteroid inhibitors of endogenous prostaglandin synthesis did not alter these effects.

0087 STUDIES ON INTRACELLULAR TRANSPORT IN THE RAT EXOCRINE PANCREAS: I. INHIBITION BY AROMATIC AMINO ACIDS IN VITRO.

(Eng.) Bieger, W.; Kern, H. F. (Dept. Anatomy, Univ. Heidelberg, Im Neuenheimer Feld 307, D-6900 Heidelberg, Germany). *Virchows Arch.* [*Pathol. Anat.*] 367(4):289-305; 1975.

The ability of natural and modified aromatic amino acids (phenylalanine, tryptophan, *p*-chlorophenylalanine, and *p*-fluorophenylalanine) to induce paracrystal formation in the rough endoplasmic reticulum (RER) of isolated male Wistar rat pancreatic lobules and the affect on the secretory process in the exocrine cell were studied. *In vitro* incubation of rat pancreatic lobules in the presence of 10 mM of the four aromatic amino acids induced paracrystal formation in the cisternal space of the RER and in the acinar lumen. Aggregation of secretory material in transitional elements of the RER suggests tubular connection to the Golgi complex. Paracrystal formation was correlated with a disturbance of the three major phases in the secretory process of the exocrine cell. Incorporation of radioactive amino acids into proteins was inhibited by 10 mM phenylalanine and tryptophan by 20 and 50%, resp., and by *p*-chlorophenylalanine at 1 and 10 mM concentrations by 50 and 75%, resp. The inhibition of protein synthesis was not due to a reduced intracellular concentration of radioactive precursor amino acids. Intracellular transport of newly synthesized proteins as studied by a radioassay for zymogen discharge and by cell fractionation was similarly inhibited by 10 mM phenylalanine, tryptophan, or *p*-chlorophenylalanine (20, 30, and 40%, resp.). Discharge of zymogens as measured by the secretion of amylase stimulated with 5 x 10^{-6} M carbamylcholine was reduced by 20% if 10 mM phenylalanine, tryptophan or *p*-chlorophenylalanine were present in the medium. On sodium dodecylsulfate gel electrophoresis, paracrystalline proteins showed the same electrophoretic pattern as the content of zymogen granules. The results demonstrate that paracrystals are formed in the RER, the Golgi complex, and in the acinar lumen. It was concluded that the paracrystals in the RER of exocrine pancreatic cells are not precipitated from aromatic amino acids, but may arise from aggregation of normal secretory proteins.

0088 THE EFFECT OF PROTEASE INHIBITORS ON PANCREATIC AND SERUM TRYPSIN AND LIPASE ACTIVITIES IN RATS WITH ACUTE PANCREATITIS.

(Rus.) Khudolei, I. F.; Levitskii, A. P.; Synovets, A. S. (N. I. Pirogov Medical Inst., Odessa, USSR). *Vopr. Med. Khim.* 21(3):296-299; 1975.

0089 CHANGES IN EXOCRINE PANCREATIC SECRETION PRODUCED BY VARIOUS DRUGS: AN EXPERIMENTAL STUDY.

SECRETION AND METABOLISM

Hepatobiliary Tract

0090 CHARACTERISTICS OF HUMAN EMBRYONIC HEPATOCYTES CULTIVATED IN VITRO.

(Rus.) Eraizer, T. L.; Grinberg, K. N.; Vorsanova, S. G. (USSR Acad. Medical Sci., Moscow, USSR). *Bull. Exp. Biol. Med.* 79(15):123-125; 1975.

A simple and reproducible method of cultivating liver cells from 7 to 12-week-old human embryos in a monolayer was developed. The liver was washed with a medium of 80% glutamine, 20% embryonic calf serum, and, in the beginning stages of cultivation, 150 mg/ml of prednisolone. The surrounding connective tissue was removed and the liver was ground in a 1:1 mixture of trypsin and versene. After 30 min of incubation at 36.5 C, the liver was forced through a pipet into the medium, the mixture was centrifuged for 10 min at 2,000 rpm, and the precipitate was resuspended in an additional amount of medium. The cells (1-3 x 10^6) were placed in 4 ml of medium on a dish and cultivated at 36.5 C in an atmosphere with 7% CO_2. On the third day, 0.12 U/ml of insulin was added. The medium was changed every 3 days. The culture showed the capacity for limited growth, displayed a viability of 4-6 weeks without being subcultured, and retained some specific characteristics: synthesis of serum protein (albumin and α-fetoprotein), a significant amount of glycogen, a high activity of monoamine oxidase, and a characteristic response to a high concentration of glucocorticoids. The authors suggest that these properties may be useful as markers for genetic experiments.

0091 PURIFICATION AND CHARACTERIZATION OF A LIVER SPECIFIC ANTIGEN. (Eng.) Mihas, A. A.; Hirschowitz, B. I.; Saccomani, G. (Div. Gastroenterology, Univ. Alabama Birmingham, Birmingham, AL 35294). *J. Immunol.* 116(5):1228-1235; 1976.

A liver-specific antigen (F-antigen) previously demonstrated in saline extracts of BALB/c mouse liver by double immunodiffusion was isolated and characterized. The antigen had an immunoelectrophoretic mobility similar to that of serum β_2-globulins, was relatively thermolabile, and was precipitated at a 30-70% saturated ammonium sulfate concentration. Gel-filtration on Sephadex G-200 revealed liver-specific antigenicity in the second peak. Ion-exchange chromatography on DEAE-Sephadex A-50 revealed four peaks, of which only the third one exhibited liver-specific antigenicity. This active peak contained 11 polypeptides on sodiumdodecyl sulfate (SDS) polyacrylamide gel electrophoresis. After electrophoresis on acrylamide gel in the absence of SDS, antigenic activity was detected on one fast-moving band. Extraction of the protein band followed by SDS gel electrophoresis showed one major component of molecular weight 75,000 and two minor bands of molecular weight 72,000 and 93,000, resp. The results indicate that the antigen is a protein or is closely associated with a protein composed of three polypeptides.

0092 BILIARY LIPID COMPOSITION IN EARLY CHILDHOOD. (Eng.) Von Bergmann, J.; Von Bergmann, K.; Hadorn, B.; Paumgartner, G. (Dept. Clinical Pharmacology, Univ. Berne, Murtenstrasse 35, 3008 Berne, Switzerland). *Clin. Chim. Acta* 64(3):241-246; 1975.

The biliary lipid composition was studied in 11 children without hepatic or gastrointestinal disease aged 15-54 months. The molar percentages of cholesterol, bile acids, and phospholipids in the biliary lipid mixture averaged 5.0, 80, and 15%, resp. Cholic, chenodeoxycholic, deoxycholic, and ursodeoxycholic acid comprised 48, 45, 4, and 3% of total bile acids, resp. A comparison with data reported for the adult reveals that the molar percentage of cholesterol is relatively low in early childhood. It is suggested that this factor is responsible for the low incidence of cholesterol gallstones in this age group.

0093 THE ESTIMATION OF PHOSPHOLIPIDS IN BILE. (Eng.) Murison, J.; Festi, D.; Ross, P. E.; Bouchier, I. A. D. (Ninewells Hosp., Medical Sch., Dundee, DD1 9SY, U.K.). *Clin. Chim. Acta* 68(2):159-166; 1976.

Total and lipid phosphorus were measured in the duodenal aspirate of 24 fasting subjects following an i.v. injection of cholecystokinin (100 U) to determine whether the introduction of a lipid extraction step affects the bile acid/phospholipid/cholesterol ratio. The lipid phosphorus values were lower than the total phosphorus, a difference most pronounced in dilute samples. Storage at -20 C over 4 weeks resulted in a loss of over 50% lipid phosphorus. These alterations in the lipid phosphorus affected the calculation of biliary phospholipid and the saturation index of cholesterol in bile, causing it to be erroneously elevated. It is concluded that analysis of bile samples should be undertaken on freshly obtained samples and should include a preliminary step for the extraction of lipids.

0094 LIVER CELL PLASMA MEMBRANE LIPIDS AND THE ORIGIN OF BILIARY PHOSPHOLIPID. (Eng.) Yousef, I. M.; Bloxam, D. L.; Phillips, M. J.; Fisher, M. M. (Dept. Pathology, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Can. J. Biochem.* 53(9): 989-997; 1975.

The source and mechanism of biliary phospholipid secretion were studied in male Wistar rats to determine whether the bile canalicular membrane differs in terms of composition and phospholipid metabolism from the remainder of the plasma membrane not directly involved in bile secretion. The hepatocyte plasma membranes of fed rats were separated into a fraction rich in bile canaliculi by discontinuous sucrose density gradient ultracentrifugation and a plasma membrane fraction. Ultrastructurally, the bile canalicular fraction consisted almost exclusively of intact bile canaliculi with their contiguous membranes. The remaining plasma membrane fraction consisted primarily of vesicles and sheets of membranes free from bile canaliculi. The bile canalicular membrane fraction contained relatively more total lipid, cholesterol, and phospholipid, and less protein. The phospholipid composition of the two fractions was the same, but the specific activity of the bile canalicular membrane phospholipids, up to 12 hr following *in vivo* administration of [2-^{3}H]glycerol, was always significantly greater than that of the remaining plasma membranes, and showed a biphasic response not found in the latter. The specific activity of the phosphatidylcholine, phosphatidylethanolamine, and lysophosphatidylcholine of the bile canalicular membranes rose to a peak within 40 min after administration of the label, fell sharply, and then rose to a second peak after 120 min. The specific activity of the sphingomyelin and phosphatidylserine plus phosphatidylinositol of the bile canalicular membranes and of all the phospholipids of the remaining plasma membranes did not show the biphasic pattern but increased steadily to reach a maximum at 120 min. The specific activity of biliary phosphatidylcholine followed a pattern identical to that of the phosphatidylcholine, phosphatidylethanolamine, and lysophosphatidylcholine of the bile canalicular membrane fraction. The average rate of turnover of phospholipid in the bile canalicular membranes was considerably greater than that in the remaining plasma membrane and other cell membrane fractions. The results indicate that the phospholipid of the bile canalicular membranes exists in two or more pools, turning over at different rates, and they support the concept that biliary phospholipid is derived from the bile canalicular membrane. The results also suggest that bile canalicular phospholipid may be derived from two different sources in contrast to the remaining plasma membrane.

0095 BILIARY LECITHIN SECRETION. II. EFFECTS OF DIETARY CHOLINE AND BILIARY LECITHIN SYNTHESIS. (Eng.) Robins, S. J.; Armstrong, M. J. (Veterans Admin. Hosp., Boston, MA). *Gastroenterology* 70(3):397-402; 1976.

Studies were performed to determine if the dietary content of choline influences biliary lecithin synthesis and secretion in the rat. Male Sprague-Dawley rats were fed either a choline-deficient diet or diets supplemented with 0.5% choline or 5.0% choline and studied after 2-3 weeks. Synthesis was at least 50% greater (as determined by ^{32}P incorporation into bile lecithin) in animals supplemented with 5.0% choline than in deficient animals. Changes in dietary choline produced no change in bile salt pool size or secretion rate. However, with each increment in dietary choline, biliary lecithin as well as cholesterol secretion rates were significantly increased. The results demonstrate that although bile salt is required for biliary lecithin secretion, the magnitude of secretion is dependent upon the extent of biliary lecithin synthesis, which in turn may be regulated by the amount of dietary choline. The results further indicate that biliary cholesterol secretion is more closely linked to lecithin than to bile salt secretion. These findings suggest that lecithin secretion might be independently manipulated when bile salt is deficient to achieve enhanced biliary cholesterol transport.

0096 BIOSYNTHESIS OF CHOLIC ACID IN RAT LIVER: 24-HYDROXYLATION OF 3α,7α,12α-TRIHYDROXY-5β-CHOLESTANOIC ACID. (Eng.) Gustafsson, J. (Dept. Chemistry, Karolinska Institutet, Stockholm, Sweden). *J. Biol. Chem.* 250(20):8243-8247; 1975.

The properties of an efficient 24-hydroxylating system consisting of the microsomal fraction and the 100,000 x *g* supernatant fluid of male Sprague-Dawley rat liver homogenate fortified with ATP were described. Conversion of 3α,7α,12α-trihydroxy-5β-[7β-^{3}H]cholestanoic acid into 3α,7α,12α,24-tetrahydroxy-5β-cholestanoic acid in rat liver was catalyzed either by the mitochondrial fraction fortified with the 100,000 x *g* supernatant fluid or the microsomal fraction fortified with 100,000 x *g* supernatant fluid and ATP. The microsomal system was more active than the mitochondrial system. With the microsomal system the rate of reaction was considerably faster with free 3α,7α,12α-trihydroxy-5β-cholestanoic acid as substrate than with the corresponding coenzyme A ester. Addition of coenzyme A inhibited the activity. Addition of cofactors other than ATP (NADPH, NADH, NADP, NAD, FMN, FAD, or cyclic AMP) and coenzyme A did not markedly influence the reaction. The 100,000 x *g* supernatant fluid could be substituted with a protein fraction obtained by ammonium sulfate precipitation and Sephadex chromatography of the 100,000 x *g* supernatant fluid. The reaction was not catalyzed by a mixed function oxidase since there was no incorporation of ^{18}O into the product when the reaction was performed in an atmosphere containing $^{18}O_2$. There was almost complete inhibition when the reaction was performed in an atmosphere consisting of nitrogen, indicating that oxygen may be obligatory for the reaction. Carbon monoxide did not inhibit the reaction. One atom of deuterium was incorporated into the product when the reaction was performed in a medium containing deuterated water. In contrast to the microsomal system, the mitochondrial system was not stimulated by the addition of ATP and was not inhibited by coenzyme A. The coenzyme A ester of 3α,7α,12α-trihydroxy-5β-cholestanoic acid was 24-hydroxylated more efficiently than the free acid. It is concluded that microsomal 24-hydroxylation of 3α,7α,12α-trihydroxy-5β-cholestanoic acid involves the combined action of a desaturase and a hydratase. The reaction catalyzed by the hydratase appears to be stereospecific since the 24α epimer of 3α,7α,12α-trihydroxy-5β-cholestanoic acid was the predominant product.

0097 METABOLISM OF BILE ALCOHOLS IN THE PERFUSED RABBIT LIVER. (Eng.) Cohen, B. I.; Kuramoto, T.; Rothschild, M. A.; Mosbach, E. H. (Public Health Res. Inst. City New York, Inc., New York, NY 10016). *J. Biol. Chem.* 251(9):2709-2715; 1976.

The mechanism and sequence of side chain hydroxylation of cholesterol in bile acid synthesis was studied in isolated perfused male New Zealand rabbit liver and the importance of 26- and 25-hydroxylation in cholic acid biosynthesis was compared. [*G*-^{3}H]-cholic acid was formed when the liver was perfused with 5β-[*G*-^{3}H]cholestane-3α,7α-diol, 5β-[*G*-^{3}H]cholestane-3α,7α,12α-triol, and 5β-[*G*-^{3}H]cholestane 3α,7α,26-triol. No [*G*-^{3}H]chenodeoxycholic acid was detected in the bile. These findings indicate that potential precursors of chenodeoxycholic acid were hydroxylated at position 12α either subsequent to or before hydroxylation of the cholesterol side chain. In addition, no other intermediates (tetrahydroxy or pentahydroxy bile alcohols) were found in the bile when these compounds were perfused in the liver. Bile acid precursors were detected in bile when the rabbit liver was perfused with 5β-[24-^{14}C]cholestane-3α,7α,25-triol. The 5β-[24-^{14}C]cholestane-3α,7α,25-triol was hydroxylated in the liver at the 12α position to yield the corresponding 5β-cholestane-3α,7α,12α,25-tetrol. The tetrol was further metabolized to a series of pentols (5β-cholestane-3α,7α,12α,22,25-pentol, 5β-cholestane-3α,7α,12α,23,25-pentol, 5β-cholestane-3α,7α,12α,24,25-pentol, and 5β-cholestane-3α,7α,12α,25,26-pentol). The major bile acid obtained from the perfusion of the 5β-cholestane-3α,7α,12α,25-triol was cholic acid. These experiments indicate that 12α-hydroxylation can occur in the rabbit liver after hydroxylation of the cholesterol side chain at either C-25 (5β-cholestane-3α,7α,25-triol) or C-26 (5β-cholestane-3α,7α,-26-

LIBRARY U. OF I.

triol). Apparently, the rabbit can form cholic acid by the classical 26-hydroxylation pathway and by 25-hydroxylated intermediates.

0098 MECHANISM OF THE STIMULATORY EFFECT OF FRUCTOSE ON ETHANOL OXIDATION IN PERFUSED RAT LIVER. (Eng.) Scholz, R.; Nohl, H. (Institut fur Physiologische Chemie, Physikalische Biochemie und Zellbiologie der Ludwig-Maximilians-Universitat Munchen, Goethestrasse 33, D-8000 Munchen 2, W. Germany). *Eur. J. Biochem.* 63(2):449-458; 1976.

The quantitative relation between the stimulated rate of ethanol oxidation and the net energy utilization due to fructose metabolism was studied in livers from fasted Wistar rats perfused with Krebs-Henseleit-bicarbonate buffer in a nonrecirculating system. Two series of experiments were performed: (a) ethanol was infused with stepwise increasing concentrations (0.1-20 mM) in the presence of 4 mM fructose, and (b) fructose was infused with stepwise increasing concentrations (0.5-10 mM) in the presence of 2 mM ethanol. From measured metabolic rates, energy-rich phosphates consumed for fructose metabolism, which were provided from oxidative phosphorylation ($\Delta \sim P$), and reducing equivalents derived from stimulated ethanol utilization, which were disposed by mitochondrial oxidation ($\Delta 2H$), were calculated. Under the various conditions studied, a linear relationship between these parameters was observed. The ratio $\Delta \sim P/\Delta 2H$ was about 2.0. The authors suggest that fructose stimulates ethanol oxidation indirectly by increasing the energy consumption of the liver due to the production of glucose and/or urea from fructose. Consequently, the rate of oxidative phosphorylation is increased; therefore, the capacity of the respiratory chain for oxidizing reducing equivalents derived from ethanol is enhanced. These data support the hypothesis that the rate of ethanol oxidation depends upon the rate of hepatic energy consumption in a given metabolic state.

0099 ABSORPTION OF CHOLESTEROL BY THE GALLBLADDER. (Eng.) Neiderhiser, D. H.; Harmon, C. K.; Roth, H. P. (Veterans Administration Hosp., Cleveland, OH 44106). *J. Lipid Res.* 17(1): 117-124; 1976.

[4-^{14}C]cholesterol (1-300 nM) dissolved in 1 ml of guinea pig bile was instilled into the *in situ* guinea pig gallbladder to study the absorption of cholesterol by the gallbladder. The bile contained 7 μmol/ml bile acid, 27 nmol/ml lecithin, and 8 nmol/ml cholesterol. To this bile, the radioactive cholesterol, 0-1 μmol/ml egg lecithin, and 100 μg/ml BSP were added. After 1 nM [4-^{14}C]cholesterol was instilled in bile without added lecithin, 77 ± 8% of the radioactivity was demonstrated in the gallbladder wall within 6 hr. The proportion of cholesterol absorbed by the gallbladder decreased as the concentration of added lecithin or bile salts was increased. Absorption of cholesterol increased as the time of instillation increased. Radioautography showed radioactivity in the mucosa, and subcellular fractionation of homogenized cells by centrifugation showed cholesterol in the mitochondrial (23 ± 4%) and microsomal (18 ± 4%) fractions. Studies on specific activity suggested that there was net absorption of cholesterol and not merely an exchange of cholesterol in the contents for cholesterol in the wall. The results indicate that significant quantities of cholesterol, but not cholesterol ester, can be absorbed by the guinea pig gallbladder. The absorbed cholesterol can be converted to cholesterol ester. The evidence suggests that in man cholesterosis is not due to the absorption by the gallbladder wall of cholesterol ester from the gallbladder lumen, but may represent an abnormality of cholesterol ester transport out of the gallbladder with an accumulation in the submucosa.

0100 HEPATIC ORGANIC ANION UPTAKE IN THE RAT. (Eng.) Scharschmidt, B. F.; Waggoner, J. G.; Berk, P. D. (Natl. Inst. Health, Bethesda, MD 20014). *J. Clin. Invest.* 56(5):1280-1292; 1975.

The hepatic uptake of bilirubin (BR), indocyanine green (ICG), and BSP was studied in 350 anesthetized Sprague-Dawley rats by determining the initial plasma disappearance rate (V) of unlabeled ICG, or of tracer quantities of [^{3}H]BR or [^{35}S]BSP injected into the jugular vein simultaneously with unlabeled BR or BSP. Similar studies were also performed involving the simultaneous injection of potential inhibitors of hepatic uptake. Hepatic uptake determined by direct tissue measurement could be accurately estimated from the plasma disappearance data. Saturation of hepatic uptake with increasing dose was readily demonstrated for each of these three organic anions, and in each instance a plot of V versus dose took the form of a rectangular hyperbola analyzable in terms of Michaelis-Menten kinetics. The saturable uptake process for BR showed a V_{max} more than 100 times the normal net transfer rate from plasma to bile. Hepatic uptake of BR, BSP, and ICG showed relatively selective, mutually competitive inhibition; glycocholic acid did not inhibit hepatic uptake of any of these substances, and finally, "counter-transport" could be demonstrated for each of the three test substances. These data are compatible with the existence of a carrier-mediated transport process for hepatic uptake of each of these three organic anions and clarify the relationship of hepatic BR uptake to its overall transport from plasma to bile.

0101 BROMSULFOPHTHALEIN UPTAKE BY ISOLATED LIVER PARENCHYMAL CELLS. (Eng.) van Bezooijen, C. F. A.; Grell, T.; Knook, D. L. (Inst. Experimental Gerontology TNO, 151 Lange Kleiweg, Rijswijk, The Netherlands). *Biochem. Biophys. Res. Commun.* 69(2):354-361; 1976.

The liver function of removing foreign compounds from the serum was investigated by measuring the uptake of [^{35}S]BSP by isolated WAG/Rij rat hepatocytes. The cells in concentrations ranging between 0.05 and 0.4 x 10^6 cells/ml were incubated with 30 nmoles [^{35}S]BSP/ml for 15 min at 37 C. An uptake of 2.87 nmoles BSP/10^6 cells was measured. The saturation of the rate of BSP uptake with increasing amounts of BSP in the medium, the ability to take up free BSP against a concentration gradient, and the dependence of the uptake mechanism on temperature and metabolic energy suggest the presence of an active carrier system for the uptake of BSP by hepatocytes.

0102 UPTAKE OF BROMOSULFOPHTHALEIN BY ISOLATED LIVER CELLS.

(Eng.) Schwenk, M.; Burr, R.; Schwarz, L.; Pfaff, E. (Institut fur Toxikoligie, Universitat Tubingen, Tubingen, W. Germany). *Eur. J. Biochem.* 64(1):189-197; 1976.

Uptake of BSP into isolated hepatocytes of male Sprague-Dawley rats was studied with special regard to the kinetics of transport. The uptake of BSP (< 50 μM) followed Michaelis-Menten kinetics only at low substrate concentrations with an apparent K_m = 7 μM and V = 2.6 ± 1.7 nmole/mg protein/min. At higher BSP concentrations there was a second mechanism of uptake indicated by the deviation from linearity in the Lineweaver-Burk plot. The activation energy of uptake was 11 kcal/mole at 10 μM BSP. Uptake was independent of metabolic energy and of the Na^+ gradient across the membrane. Metabolic inhibitors such as Actinomycin A, rotenone, and carbonylcyanide *m*-chlorophenylhydrazone had no detectable effect on BSP uptake. Taurocholate did not inhibit uptake, while indocyanine green inhibited competitively at low BSP concentrations and activated uptake at high BSP concentrations (> 20 μM). Amino acid reagents, such as dinitrofluorobenzene, mersalyl, *N*-ethylmaleimide, and dithionitrobenzene did not affect uptake at a concentration of 100 μM. No pH optimum for BSP uptake was observed in the physiological pH range. Adsorption of BSP to the liver cell membrane had two distinguishable sites with affinities $K_1 = 5.7 \times 10^{-6}$ M and $K_2 = 7 \times 10^{-5}$ M and binding capacities n_1 = 1.2 nmole/mg protein and n_2 = 7 nmole/mg protein. Adsorption was inhibited by indocyanine green. The results are consistent with the hypothesis that BSP is bound in an energy-consuming process to a translocating site, possibly in the undissociated form or as ion pair. The consecutive transfer across the membrane appears to require little additional energy.

0103 DIFFERENCES OF REABSORPTION OF UNCONJUGATED BSP AND BSP-GLUTATHIONE FROM THE RAT BILIARY TREE AFTER RETROGRADE INTRABILIARY INJECTION.

(Eng.) Dammann, H. G.; Czok, G. (I. Medizinische Universitats-Klinik der Universitat Hamburg, 2000 Hamburg 20, Martinstrasse 52, W. Germany). *Res. Exp. Med.* 165(3):181-190; 1975.

The biliary excretion of unconjugated sulfobromophthalein sodium (BSP-U) and BSP-glutathione (BSP-GSH) was studied in male Wistar rats after retrograde intrabiliary injection. BSP-GSH was excreted to a much greater extent than BSP-U within the first 5 min after retrograde administration. BSP-GSH was reabsorbed to a lesser extent than BSP-U. After 5 min the reabsorption of BSP-U and BSP-G after retrograde injection seemed to be dependent on the concentration and the contact time in the biliary tree. It is suggested that the different biliary excretion of BSP-U and BSP-GSH after i.v. injection might be explained partly by a different mode of reabsorption.

0104 BILIARY EXCRETION OF DRUGS IN THE RAT DURING LIVER REGENERATION.

(Eng.) Uesugi, T.; Bognacki, J.; Levine, W. G. (Albert Einstein Coll. Medicine Yeshiva Univ., Bronx, NY 10461). *Biochem. Pharmacol.* 25(10):1187-1193; 1976.

Alterations in liver function during liver regeneration were studied in Wistar rats by measuring bile flow and the biliary excretion of bile salts, BSP, its glutathione conjugate (BSP-GSH), phenol-3,6-dibromophthalein disulfonate (DBSP), and tartrazine (TZ). Immediately after partial hepatectomy, bile flow and bile salt secretion, expressed per gram of liver, were significantly increased. Bile flow remained high through the third day. The concentration of bile salts on the first day was significantly lower than that of controls and remained low through the fourth day, suggesting an increased osmotic potency. Plasma clearance of BSP injected i.v. (10 mg) was proportional to residual liver mass. The excretion of BSP-GSH after injection of BSP was decreased in parallel to the decrease in BSP-GSH transferase activity during liver regeneration. In contrast, the excretion of unconjugated BSP and unknown conjugates was actually increased. Biliary excretion of injected BSP-GSH was significantly decreased up to the third day postoperatively. These results suggest that some of the decreased BSP-GSH excretion after injection of BSP is attributable to the decreased activity of BSP-GSH transferase and to competition by unconjugated BSP. After partial hepatectomy, the excretion of injected BSP-GSH and DBSP, expressed per gram of liver, was about twice that of controls and thereafter rapidly returned to control levels. In contrast to the other dyes, the excretion of TZ (injected i.v., 26.7 mg) decreased in proportion to liver mass following partial hepatectomy. On the second and third day, the marked sex differences seen in controls were not observed. The results imply that BSP-GSH and DBSP are transported into the bile by a similar mechanism while the mechanism for TZ transport is considerably different.

0105 DISULFIRAM AS A TOOL IN THE STUDIES ON THE METABOLISM OF ACETALDEHYDE IN RATS.

(Eng.) Tottmar, O.; Marchner, H. (Inst. Zoophysiology, Univ. Uppsala, Box 560, S-751 22 Uppsala, Sweden). *Acta Pharmacol. Toxicol.* 38(4):366-375; 1976.

The liver acetaldehyde dehydrogenases and the acetaldehyde level in the blood during ethanol metabolism were studied *in vivo* in female Sprague-Dawley rats 24 hr after the administration of disulfiram (25-600 mg/kg). Ethanol was given i.p. as a 7.8% solution in saline at a dose of 1.7 g/kg. Acetaldehyde dehydrogenase activity and acetaldehyde concentrations in the blood were assayed spectrophotometrically and fluorimetrically, resp. High doses of disulfiram (150-600 mg/kg) caused a threefold decrease in the activity of the mitochondrial low-K_m enzyme but had no significant effects on the activity of the high-K_m enzymes present in the mitochondrial, the microsomal, and the cytosolic fractions. The concentration of acetaldehyde was threefold higher in the hepatic venous blood and fivefold higher in the peripheral blood in rats given disulfiram compared to rats given ethanol only. Low doses of disulfiram (25-50 mg/kg) decreased the activity of the low-K_m enzyme by 26%, and caused a significant increase in the liver output of acetaldehyde. The rate of ethanol elimination decreased by 35% at a high dose of disulfiram, whereas the alcohol dehydrogenase activity was not influenced. The authors suggest that the mitochondrial low-K_m enzyme has a primary role in the regulation of the hepatic output of acetaldehyde during ethanol metabolism.

0106 EFFECT OF GRADED BILIRUBIN LOADS ON BILIRUBIN TRANSPORT BY PERFUSED RAT LIVER. (Eng.) Bloomer, J. R.; Zaccaria, J. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Am. J. Physiol.* 230(3):736-742; 1976.

Features of hepatic bilirubin transport were studied in isolated perfused livers from male Wistar rats. When bilirubin was constantly infused (1.6-18.0 mg/hr) into the perfusion medium, which contained sheep RBC and 3.0 g/100 ml bovine serum albumin, the maximal excretion rate for bilirubin was 14.4 μg/min/g liver. Over a wide range of constant bilirubin infusion rates (maximum 25.9 μg/min/g liver) there was no effect on bile flow, bile acid excretion, or the pattern of bilirubin conjugates in bile. The hepatic extraction efficiency for unconjugated bilirubin from the perfusate also remained constant, averaging 26%. However, when bolus injections of bilirubin were used to produce higher levels of unconjugated bilirubin in the perfusate than could be attained during constant infusion, the disappearance rate of [^{14}C]bilirubin from the perfusate decreased with increasing bilirubin concentrations. The results indicate that the hepatic removal of unconjugated bilirubin and other organic anions is a saturable process.

0107 EFFECT OF PRIMARY BILE ACIDS ON BILE LIPID SECRETION FROM PERFUSED DOG LIVER. (Eng.) Hoffman, N. E.; Donald, D. E.; Hofmann, A. F. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Am. J. Physiol.* 229(3):714-720; 1975.

An isolated canine liver perfusion technique featuring a second dog as the pump oxygenator was used to compare biliary lipid secretion during randomized, steady-state perfusions at two different rates of cholyl taurine or chenodeoxycholyl taurine infusions. The hepatic extraction of the trihydroxy-conjugated bile acid was considerably greater than that of the dihydroxy conjugate, possibly explained by ultrafiltration experiments that indicated that cholyl taurine was less protein bound than chenodeoxycholyl taurine. Both bile acids induced phospholipid and cholesterol secretion that was linearly proportional to bile acid secretion. However, each mole of secreted chenodeoxycholyl taurine induced a greater relative secretion of phospholipid and cholesterol than did that of cholyl taurine. Thus, the two primary bile acids in the canine liver are extracted at different rates and induce biliary secretion of different relative lipid composition.

0108 EFFECT OF CHRONIC ADMINISTRATION OF CARBON TETRACHLORIDE ON COPPER, ZINC, AND MERCURY BINDING IN BILE IN RATS. (Eng.) Tichy, M.; Cikrt, M. (Inst. Hygiene and Epidemiology, Prague, Czechoslovakia). *Toxicol. Appl. Pharmacol.* 36(1):163-172; 1976.

Changes in the concentrations of endogenous copper and zinc in rat bile after CCl_4 intoxication and changes in copper and zinc binding with components of the bile were examined. CCl_4 (1 ml/kg) was given s.c. to female Wistar rats twice a week during 3 mo. After 3 mo the bile ducts were cannulated in rats of one group; whereas, the animals in another group were sacrificed, and their livers removed. Solutions of $^{64}CuCl_2$, $^{65}ZnCl_2$, or $^{203}HgCl_2$ were administered i.v. to the rats with cannulated bile ducts. CCl_4 treatment provoked changes in copper and zinc concentrations in the bile and in the liver proteins. Treatment with copper or zinc salts resulted in changes in bile components of high molecular weight. The quantity of copper bound in different bile components was not changed after CCl_4 treatment; whereas, that of zinc did change. The findings indicate that mercury is bound in bile in a different way than copper or zinc. The changes in the binding of copper and zinc with bile components in rats given CCl_4 are reflected in changes of cumulative excretion of copper and zinc *via* bile during the 24 hr following their administration.

0109 EFFECT OF METHEMOGLOBINEMIA ON CARBON TETRACHLORIDE HEPATOTOXICITY. (Eng.) Pankow, D.; Ponsold, W. (Inst. Hygiene, Martin Luther Univ., West Germany). *Toxicol. Appl. Pharmacol.* 36(1):143-150; 1976.

The effect of methemoglobinemia on CCl_4-induced hepatotoxicity in normal and adrenalectomized outbred male albino rats is studied. Four experimental groups were examined: (I) controls; (II) those injected i.p. with methemoglobin-forming compound (0.08 mmol $NaNO_2$/kg or 1 mmol hydroxylamine hydrochloride/kg as aqueous solutions; 0.8 mmol nitrobenzene/kg, 0.15 mmol *m*-dinitrobenzene/kg, 3 mmol aniline/kg, or 0.6 mmol phenylhydrazine/kg in polyethylene glycol; (III) 5.2 mmol CCl_4/kg administered by stomach tube; and (IV) 5.2 mmol CCl_4/kg and methemoglobin-forming compound 4 hr later. Methemoglobin content and the activity of glutamic-pyruvic transaminase (GPT) and leucine aminopeptidase (LAP) were assayed. LAP and GPT assayed 24 hr after CCl_4 poisoning, showed no significant increase. However, the combination of CCl_4 plus $NaNO_2$ (group IV) produced significantly higher enzyme activities (GPT, 190 ± 84 U/l; LAP, 1110 U/l) than when CCl_4 was administered alone (group III--GPT, 123 ± 65 U/l; LAP, 644 U/l). LAP assay 48 hr after CCl_4 or CCl_4 plus $NaNO_2$ administration rose from 1356-2211 U/l. In adrenalectomized rats, $NaNO_2$ did not affect the hepatotoxic response of CCl_4. When normal rats received CCl_4 and $NaNO_2$, a depression of methemoglobin formation was apparent. CCl_4 plus aniline, nitrobenzene, *m*-dinitrobenzene, phenylhydrazine, or hydroxylamine hydrochloride produced potentiating differences, however these were not always significant. CCl_4 plus methemoglobin forming compounds produced a decrease in methemoglobin percentage in all cases over methemoglobin-forming compounds alone. The results demonstrate that $NaNO_2$-induced methemoglobinemia may produce potentiation of the toxic CCl_4 response.

0110 PLASMA LIPOPROTEINS IN RATS WITH EXPERIMENTAL BILIARY OBSTRUCTION. I. A CHEMICAL STUDY. (Eng.) Calandra, S.; Montaguti, M.; Cartoni, V.; Pasquali-Ronchetti, I. (Istituto di Patologia Generale, Universita delgi Studi di Modena, Modena, Italy). *Biochim. Biophys. Acta* 409(1):1-12; 1975.

The chemical and ultrastructural changes of male Wistar rat plasma lipoproteins in acute biliary obstruction were characterized. The lipoproteins were separated on cellulose acetate strips and by agar gel electrophoresis. Delipidated lipoproteins were analyzed by polyacrylamide gel electrophoresis. The level of very low density lipoprotein (VLDL) in plasma was found to increase from two- to threefold. VLDL was determined to have a high content of phospholipids and cholesterol and a diminution of the relative content of triacylglycerols and protein. On cellulose acetate electrophoresis, VLDL showed a β-mobility. The plasma concentration of low density lipoproteins (1.019-1.063 g/ml, LDL_2) increased several-fold above control level. Phospholipids and unesterified cholesterol were the major components of this fraction, which contained only a minute amount of cholesteryl ester (4%) and triacylglycerols (10%). LDL_2 were observed to contain a component that migrated to the cathodes in 1% agar gel electrophoresis. Separation of LDL_2 by gel filtration on 2% agarose column resulted in the identification of three subfractions. Subfraction I contained a large proportion of cholesterol and triacylglycerols. Subfraction II was rich in unesterified cholesterol and phospholipids, whereas subfraction III had a chemical composition fairly similar to that of the control LDL_2. The level of high density lipoproteins (HDL) also increased after bile duct ligation. The chemical composition of HDL_2 (1.063-1.125 g/ml) was characterized by a high content of unesterified cholesterol and phospholipids and by a remarkable reduction in the content of cholesteryl esters and protein. The authors suggest that the abnormalities of plasma lipoproteins found in cholestatic rats strongly resemble those found in biliary obstruction in man.

0111 CONJUGATION OF NON-ERYTHROID BILIRUBIN IN CHRONIC EXPERIMENTAL CHOLESTASIS IN THE DOG. (Eng.) Bergan, A.; Ostrem, T.; Gjelstad, N. (Rikshospitalet, Univ. Clinic, Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(6):565-569; 1975.

The conjugation of nonerythroid bilirubin (NEB), i.e., the 10-20% of bilirubin synthesized mainly in the liver from tissue hemes, was studied in four dogs subjected to extrahepatic cholestasis of 7-14 days duration. δ-Aminolevulinic acid-5-^{14}C-HCl was injected i.v. as a NEB precursor. The appearances of unconjugated and conjugated labeled NEB as well as of the different azopigments were followed in systemic blood, liver vein blood, and thoracic duct lymph. The first NEB to appear was unconjugated; maximal concentration of unconjugated NEB in peripheral and liver vein blood was reached within 1 hr. The amount of conjugated NEB in both vascular compartments increased for 2-3 hr, after which time the degree of conjugation stabilized. The degree of conjugation was higher in liver vein than in peripheral blood for the first 2 hr. The a_0 azopigment (azobilirubin) was present in higher amounts in peripheral than in liver vein blood. All the other azopigments were present in higher amounts in liver vein blood. The results suggest that the extrahepatic NEB is brought into the liver in unconjugated form to be conjugated and returned to the blood, and that liver-produced NEB is delivered to the blood as conjugates.

0112 CYCLIC AMP IN SECRETIN CHOLERESIS: EVIDENCE FOR A REGULATORY ROLE IN MAN AND BABOONS BUT NOT IN DOGS. (Eng.) Levine, R. A.; Hall, R. C. (Upstate Medical Center, 750 East Adams St., Syracuse, NY 13210). *Gastroenterology* 70(4):537-544; 1976.

Cyclic AMP output in the bile in response to i.v. secretin was measured in 11 cholecystectomized patients, 12 baboons, and 15 dogs to determine the effect of secretin on cyclic AMP in perfusate. In addition, cyclic AMP concentration in human bile after dibutyryl cyclic AMP (DBcAMP), aminophylline, glucagon, and sodium dehydrocholate administration is documented. Secretin was given to patients with bile drainage tubes as an i.v. bolus (1 U/kg). In baboons and dogs, both secretin infusion (4 U/kg/hr) and bolus injection (1 U/kg) were used. In baboons, cyclic AMP was also determined in liver, extrahepatic duct tissue, and in perfusate from isolated segments of extrahepatic bile ducts. Secretin induced a marked choleresis in all three species. In humans, biliary cyclic AMP concentration increased an average of 68% ± 12% and in baboons fourfold, but no increase occurred in dogs. In baboons, cyclic AMP concentration increased in both bile duct tissue and perfusate from isolated bile ducts concomitant with secretin choleresis, but not in the liver. In humans the choleretic effects of sodium dehydrocholate (500 mg), aminophylline (500 mg), and glucagon (1.0 mg) were compared to dibutyryl cyclic AMP (0.25-0.3 mg/kg/min for 30-min period). All agents increased bile flow two- to threefold. Cyclic AMP concentration in bile markedly increased after glucagon and DBcAMP but not after sodium dehydrocholate and aminophylline. It is concluded that cyclic AMP is implicated in secretin choleresis in both humans and baboons, but not in dogs. The bile duct appears to be the site of cyclic AMP elaboration induced by secretin in baboons and probably is also in man.

0113 HEPATIC ARTERIAL AND PORTAL VENOUS FLOWS DURING HEMORRHAGE. (Eng.) Darle, N.; Lim, R. C., Jr. (Dept. Surgery I, Univ. Goteborg,

Goteborg, Sweden). *Eur. Surg. Res.* 7(4/5):259-268; 1975.

Changes of total liver blood flow (TLBF), portal venous, and hepatic arterial flows in the normotensive condition were investigated using a hemorrhagic model in four dogs. The dogs were bled stepwise from normal blood pressure to a pressure of 50-60 mm Hg by withdrawing 53-70% of the calculated blood volume. TLBF was measured by the xenon clearance method. Hepatic arterial blood flow was measured by electromagnetic flowmeter. Portal venous flow was calculated by subtracting hepatic arterial blood flow from TLBF. Systemic arterial blood pressure and portal venous pressure were also determined. Under normotensive conditions TLBF in mean was registered as 127 ml/min x 100 g liver tissue (25 ml/min x kg body weight). The relation between the flow value in portal vein and hepatic artery was an average of 2:3:1. There was a pronounced decrease of TLBF flow during hemorrhage. Portal venous flow decreased almost parallel to TLBF, while hepatic arterial flow decreased to a lesser extent, indicating an autoregulation in this flow bed. Hepatic arterial flow successively constituted a larger part of TLBF during hemorrhage, sometimes 65% compared to the normal value of about 30%. There was an increase of vascular resistance in the portal venous system and decreased resistance in the hepatic arterial bed. The authors suggest that if the observed circulatory events are also valid in humans, acute clamping of the hepatic artery during hemorrhagic shock could mean reduction of the already reduced TLBF by a further 65%.

0114 RELATIONSHIP OF SPLANCHNIC BLOOD FLOW AND PORTAL VENOUS RESISTANCE TO ELEVATED PORTAL PRESSURE IN THE DOG. (Eng.) Witte, C. L.; Tobin, G. R.; Clark, D. S.; Witte, M. H. (Univ. Arizona Coll. Medicine, Tucson, AZ). *Gut* 17(2):122-126; 1976.

In situ perfusion of the splanchnic circuit was carried out in 12 freshly killed dogs at varying perfusion rates and degrees of acute and chronic portal vein constriction to determine the relation of splanchnic blood flow and portal venous resistance to elevated portal pressure. In six normal dogs, portal pressure averaged 8.8 mm Hg and portal flow 658 ml/min. In the absence of portal vein constriction, increasing splanchnic perfusion to 1,800 ml/min, minimally raised portal pressure (12.8 mm Hg). With progressive acute constriction of the portal vein, however, comparable perfusion rates led to progressively higher portal pressure levels and with over 90% constriction, portal pressure was over 30 mm Hg with minimal elevation in splanchnic flow rate. In six other dogs alive 9 weeks after placement of an ameroid constrictor on the portal vein, portal pressure averaged 13.6 mm Hg or slightly higher than in normal dogs. Mesenteric venography and necropsy findings uniformly demonstrated 90% occlusion of the portal vein with extensive portasystemic collateralization. With increased perfusion of the splanchnic bed, portal pressure rose rapidly to about 35 mm Hg with a flow rate of 1,800 ml/min. These data suggest that in disorders where resistance to transhepatic portal flow is marked, a small increment in splanchnic blood flow, which normally exerts little or no influence on portal pressure, promotes profound portal hypertension and may account for spontaneous rupture of esophageal varices. Where resistance to transhepatic portal flow is mild but splanchnic blood flow is markedly hyperdynamic, reducing inflow may be sufficient to ameliorate extreme portal hypertension and its sequelae.

0115 THE EFFECTS OF PORTACAVAL SHUNTING AND PORTACAVAL TRANSPOSITION ON SERUM IgG LEVELS IN THE RAT. (Eng.) Benjamin, I. S.; Ryan, C. J.; Biol, L. I.; McLay, L. C.; Horne, C. H. W.; Blumgart, L. H. (Glasgow Royal Infirmary, Glasgow, Scotland). *Gastroenterology* 70(5):661-664; 1976.

Changes in the serum levels of immunoglobulin G (IgG, γ_2-globulin) and the liver-derived serum proteins, albumin, and slow α_1-globulin, were studied in male Sprague-Dawley rats over a 5-week period after portacaval shunt, portacaval transposition, or sham operation. In rats subjected to end-to-side portacaval shunt and to portacaval transposition, serum IgG levels rose progressively by approximately 100% over the 5-week period. During the same period, sham-operated control animals showed only the increase expected with age. Rats with a portacaval shunt showed a greater fall in body weight and liver weight than did those with a portacaval transposition, and also showed a greater fall in levels of liver-synthesized proteins. Albumin fell 20% for the animals with portacaval transposition and 30% for those with portacaval shunt. Slow α_1-globulin rose postoperatively in all three groups, but declined progressively from the elevated level after the first week in animals with portacaval shunt. Serum enzyme levels (SGOT, SGPT, alkaline phosphatase, lactate dehydrogenase, and creatine kinase) were markedly elevated during the first 48 hr after portacaval shunting, whereas after portacaval transposition the elevation was very small. Over the following 5 weeks, enzyme elevations continued to be marginally greater in the portacavally shunted animals. The results support the hypothesis that hypergammaglobulinemia is due to the shunting of antigen-rich portal blood past the reticuloendothelial cells of the liver, and that hepatocellular damage does not play a major role in this process. The authors suggest that the etiology of hypergammaglobulinemia in chronic liver disease in man may be similar.

0116 THE EFFECT OF PROLONGED ADMINISTRATION OF ALLYLISOPROPYLACETYLUREA TO RATS ON CYTOCHROME P-450 AND OTHER LIVER HAEMOPROTEINS. (Eng.) Rentsch, G.; Johnston, A. (Medical Biological Res. Div., Sandoz Ltd., Basel, Switzerland). *Xenobiotica* 6(3):151-157; 1976.

The effects during long-term administration of, and recovery from, allylisopropylacetylurea (400 mg/kg/day in two equal s.c. injections for 21 days) on the hepatic drug metabolizing system of male Sandoz OFA-SPF rats were investigated. In the liver, cytochromes P-450 and b_5, catalase, and 5-aminolevulinic acid synthetase were measured. Serum glutamate-pyruvate transaminase, glutamate-oxalacetate transaminase, and alkaline phosphatase were determined to assess cell damage, while urinary coproporphyrin and uroporphyrin were measured to assess the degree of porphyria. Serum glutamate-pyruvate and -oxalate transaminases and alkaline phosphatase were within normal range, except for a significant increase when compared to controls during days 10 and 18. In the liver, the lowering of cytochrome P-450 and catalase paralleled an increase in 5-aminolevulinate synthetase. Cytochrome b_5 was only marginally affected. The rats recovered well from long-term treatment with high doses of allylisopropylacetylurea and reverted to normal values for parameters measured after discontinuation of the drug, indicating that this compound does not inflict permanent damage in the rat. A mechanism for the intracellular action of allylisopropylacetylurea on cytochrome P-450 and other heme-containing compounds is presented.

0117 SPECIES DIFFERENCES IN CARBON TETRACHLORIDE-INDUCED HEPATOTOXICITY: THE ROLE OF CCl_4 ACTIVATION AND OF LIPID PEROXIDATION. (Eng.) Diaz Gomez, M. I.; de Castro, C. R.; D'Acosta, N.; de Fenes, O. M.; de Ferreyra, E. C.; Castro, J. A. (Laboratorio de Quimica Bio-Toxicologica, CITEFA, Zufriategui y Varela, Villa Martelli, Pcia de Buenos Aires, Argentina). *Toxicol. Appl. Pharmacol.* 34(1):102-114; 1975.

Experiments were carried out to establish a possible correlation between the extent of carbon tetrachloride activation to bound CCl_4 in the livers of different animal species and the liver microsomal content of both cytochrome P-450 (P-450) and cytochrome P-450 reductase activity. CCl_4-induced liver necrosis was more intense in the mouse (A/J strain) than in the guinea pig or the Syrian Golden hamster, which were more susceptible than the rat (Sprague-Dawley). The chicken was resistant to CCl_4. Liver microsomal P-450 reductase activity decreased in the following sequence: hamster > guinea pig > mouse > rat > chicken. The extent of the irreversible binding of ^{14}C from $^{14}CCl_4$ to cellular components decreased as follows: mouse = hamster > guinea pig > rat > chicken, while the intensity of the CCl_4-induced lipid peroxidation decreased in the order: rat > hamster = guinea pig > chicken = mouse. The results suggest a better parallelism between intensity of irreversible binding to cellular components and necrosis than between lipid peroxidation and necrosis. The necrotic process in the mouse was observed in absence of lipid peroxidation during the entire 24-hr period of intoxication. It was not possible to absolutely correlate the extent of the irreversible binding to microsomal lipids in the different species with either the characteristics of the spectral changes produced by CCl_4 by interaction with P-450 or with the content of P-450 or that of the P-450 reductase activity.

0118 QUANTITATIVE ANALYSIS OF METABOLISM OF HEPATIC TRIGLYCERIDE IN ETHANOL-TREATED RATS. (Eng.) Abrams, M. A.; Cooper, C. (Dept. Biochemistry, Case Western Reserve Univ., Cleveland, OH 44106). *Biochem. J.* 156(1):33-46; 1976.

The extent to which ethanol influences delivery of unesterified fatty acid of serum to liver was studied in male Sprague-Dawley rats. After an i.p. injection of ethanol (0.7 or 2.1 g/kg) caused the reversible, dose-dependent accumulation of hepatic triglyceride, ethanol (2.1 g/kg) was observed to have no effect on the flux of unesterified fatty acid of serum (4.3 μmol/min/100 g body weight). However, either dose increased the fraction of the total flux going to the liver from 0.16 to 0.27 as rapidly as could be measured (30 sec), and it remained elevated until all ethanol was cleared from the blood. The fraction of the total radioactivity in lipids of liver that was in triglyceride increased linearly for 1 hr from 30 to 50%, and there was a simultaneous decrease in phospholipid from 60 to 40%. The rate of synthesis of hepatic triglyceride derived directly from unesterified fatty acid of serum was calculated by using the flux rate of unesterified fatty acid in serum, the fractional hepatic uptake of this flux, and the percentage of liver fatty acid esterified to triglyceride. This contribution was related to the total synthetic rate of hepatic triglyceride (rate of accumulation + rate of release) to determine quantitatively how much of the developing fatty liver is attributable to increased uptake of unesterified fatty acid of serum. At the higher dose of ethanol, about half of the accumulating triglyceride is derived from this source, whereas with the lower dose of ethanol, it can account for all of the build-up.

0119 MECHANISM OF INCREASED HEPATIC UPTAKE OF UNESTERIFIED FATTY ACID FROM SERUM OF ETHANOL-TREATED RATS. (Eng.) Abrams, M. A.; Cooper, C. (Dept. Biochemistry, Case Western Reserve Univ., Cleveland, OH 44106). *Biochem. J.* 156(1):47-54; 1976.

The mechanism by which livers of ethanol-treated rats take up an increased fraction of the total flux of unesterified fatty acid in serum was studied to determine whether an acute dose of ethanol (i.p., 0.7 or 2.1 g/kg) can effect hepatic blood flow. Ethanol (0.7 g/kg) caused a twofold rise in the serum content of liver, and this serum was in rapid equilibrium with the general circulation. The fractional hepatic uptake from serum of a group of compounds with varying uptake mechanisms and metabolic fates was studied in control and ethanol-treated animals. All compounds tested, including unesterified fatty acid, showed an enhanced uptake when ethanol was given. For carbon tetrachloride (0.5-7.5 μl/100 g), a dose-response relationship was established between the amount administered, the amount taken up by liver, and the amount metabolized. This dose of ethanol caused the liver to receive an increased flow of blood, and as a result all compounds present and capable of being taken up by liver were taken up at an increased rate. Hepatic blood flow was measured by a technique that monitors the rate of clearance of a colloidal lipid emulsion. Ethanol increased hepatic blood flow by about 60%. This

LIBRARY U. OF I.

effect of ethanol on hepatic blood flow provides an explanation for the fatty liver and the synergistic effect between an acute dose of ethanol and carbon tetrachloride.

0120 EFFECTS OF A SINGLE INTOXICATING DOSE OF ETHANOL ON THE VITAMIN PROFILE OF ORGANELLES IN RAT LIVER AND BRAIN. (Eng.) Frank, O.; Luisada-Opper, A.; Sorrell, M. F.; Zetterman, R.; Baker, H. (New Jersey Medical Sch., 88 Ross St., East Orange, NJ 07018). *J. Nutr.* 106(5):606-614; 1976.

The effects of a single, p.o., intoxicating dose of ethanol (EtOH, 9 g/kg) on the distribution of water- and fat-soluble vitamins in various subcellular fractions of eight livers and eight brains from 16 male Sprague-Dawley rats were surveyed. Both organs showed redistribution of vitamins among the various organelles after EtOH was given in comparison to eight controls. In saline-treated animals the nucleus and cytosol of the liver contained the highest proportion of all vitamins, and the microsomes and lysosomes contained the least. As compared to controls, EtOH ingestion generally caused the mitochondria and microsomes to accumulate vitamins, while vitamins in the lysosomes were decreased. Except for thiamin and niacin, the whole brain vitamins were higher than those in controls; they were primarily concentrated in the brain nucleus and mitochondria. It is concluded that changes in the organelle vitamin content of the liver are the result of EtOH injury. The simultaneous attempt to repair the injury is manifested by the sequestration of vitamins in the organelles of EtOH-treated animals as compared to controls.

0121 PATHWAYS RESPONSIBLE FOR THE ADAPTIVE INCREASE IN ETHANOL UTILIZATION FOLLOWING CHRONIC TREATMENT WITH ETHANOL: INHIBITOR STUDIES WITH THE HEMOGLOBIN-FREE PERFUSED RAT LIVER. (Eng.) Thurman, R. G.; McKenna, W. R.; McCaffrey, T. B. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA 19174). *Mol. Pharmacol.* 12(1):156-166; 1976.

The perfused rat liver was used to study the metabolism of the adaptive increase in ethanol metabolism resulting from chronic treatment with ethanol. Female Sprague-Dawley rats received ethanol in a semiliquid diet or in a sucrose solution for 5-7 weeks. Ethanol metabolism was activated 60% over controls as a result of chronic ethanol treatment. Rates in both groups were nearly completely abolished (less than 16 μmoles/g/hr) by 4-methylpyrazole. Similar inhibition was observed with inhibitors of the mitochondrial respiratory chain (rotenone and antimycin A) and atractyloside. The adaptive increase was completely abolished with ouabain, an inhibitor of the sodium-plus potassium-activated ATPase. Basal respiratory rates (127 μmoles/g/hr) were markedly elevated (205 μmoles/g/hr) as a result of treatment with ethanol. However, succinate-dependent respiration of isolated mitochondria was either unaffected or slightly depressed in livers from ethanol-treated animals. There was a direct relationship between oxygen uptake and ethanol oxidation in the perfused liver. These data are consistent with the hypothesis that the primary event in enhanced ethanol metabolism following chronic treatment with ethanol is an increase in ATPase activity, most likely due to the sodium pump. The ADP produced from enhanced ion movement enters the mitochondrial space and stimulates electron transport and oxygen uptake. As a consequence of these events, a greater rate of NADH reoxidation occurs, resulting in a greater rate of production of NAD^+, which stimulates ethanol oxidation via alcohol dehydrogenase.

0122 SYNERGISTIC ACTION OF GLUCAGON AND INSULIN IN REGULATION OF HEPATIC REGENERATION. (Eng.) Bucher, N. L. R.; Swaffield, M. N. *In: Advances in Enzyme Regulation. Proceedings of the Thirteenth Symposium on Regulation of Enzyme Activity and Synthesis in Normal and Neoplastic Tissues held at Indiana University School of Medicine, Indianapolis, Indiana, October 7 and 8, 1974.* Pergamon Press. (Oxford, England): vol. 13, pp. 281-293; 1975.

Male Sprague-Dawley rats eviscerated of portal splanchnic organs and deprived of a portal blood supply were maintained by continuous i.v. infusion to study the roles of pancreatic hormones in hepatic regeneration. [^{3}H]thymidine (50 μCi, i.v.) was injected 1 hr before the termination of the experiment to assay regenerative activity. A regenerative response to partial hepatectomy was observed when the rats were given only electrolytes and glucose, as evidenced by a significant rise in the rate of hepatic DNA synthesis. The response was delayed by about 24 hr and diminished by about two-thirds in comparison to normal controls. Addition of insulin (0-8.0 U/kg/24 hr with glucose) or glucagon (0-3.0 U/kg/24 hr with FreAmine) had little effect when given separately. In combination, however, the hormones were capable of fully restoring the DNA biosynthetic rate to normal, even when the start of the hormone treatment was delayed for 6-7 hr after the partial hepatectomy. The modest but significant regenerative activity inducible in the near total absence of pancreatic hormones and the nondeleterious effect of delaying insulin and glucagon treatment suggest that additional hormonal or humoral agents may be involved in the initial activation of hepatic regeneration. The precipitous fall in portal vein insulin levels to near zero observed during the first several hours of regeneration in normal (noneviscerated) rats further supports this view, as does the preliminary finding that infusion of insulin and glucagon into eviscerated but nonhepatectomized control rats failed even minimally to excite DNA synthesis in intact livers. Thus, the pancreatic hormones, acting in synergy, appear to be the major regulators of the rate and possibly also of the magnitude of the proliferative process.

0123 EFFECTS OF CHOLERA ENTEROTOXIN, GLUCAGON, AND DIBUTYRYL CYCLIC AMP ON RAT LIVER ALKALINE PHOSPHATASE, BILE FLOW, AND BILE COMPOSITION. (Eng.) Baker, A. L.; Kaplan, M. M. (Univ. Chicago Hosp., 950 E. 59th St., Chicago, IL 60637). *Gastroenterology* 70(4):577-581; 1976.

Experiments were carried out to examine (a) whether or not cholera enterotoxin produces changes in bile flow or bile composition similar to the changes in fluid and electrolyte secretion produced in the intestine, (b) whether changes in bile flow or bile composition might provide some insight into the function of rat liver alkaline phosphatase, and (c) the hypothesis that the function of hepatic alkaline phosphatase is to mediate the secretion of choline into bile. Cholera enterotoxin (45 μg/250 g, i.v.), caused a sixfold rise in the activity of liver alkaline phosphatase in male CD rats within 12 hr. There was no change in bile volume or in the concentration or total bile content of Na^+, K^+, HCO_3^-, or Cl^- for 36 hr after the administration of cholera toxin. However, bile phospholipid output fell markedly from a control level of 15.0 ± 1.0 μmol/6 hr to a low level of 4.0 ± 1.2 μmol/6 hr in the 12- to 18-hr collection ($p<0.001$). There was a similar fall in bile acid secretion, from a control value of 9.8 ± 0.4 μmol/6 hr to 4.1 ± 0.9 μmol in the 12- to 18-hr period ($p<0.01$). The cholera effect was prolonged. Bile acid and phospholipid secretion rates did not return to control values until 30-36 hr after the administration of cholera enterotoxin. The cholera toxin-induced reductions in bile acid, and phospholipid secretion into bile did not appear to be mediated by adenyl cyclase or cyclic AMP, as neither glucagon nor dibutyryl cyclic AMP had any effect on the secretion into bile of bile acids or phospholipid. The administration of cholera toxin was not associated with any increase in the secretion of free choline into bile. Glucagon and dibutyryl cyclic AMP also had no stimulatory effect on the secretion of free choline into bile. The results do not support the hypothesis that the main function of rat liver alkaline phosphatase is to facilitate the excretion of free choline into bile.

0124 EVIDENCE THAT D-GLUCARO-1,4-LACTONE SHORTENS THE PHARMACOLOGICAL ACTION OF DRUGS BEING DISPOSED VIA THE BILE AS GLUCURONIDES.

(Eng.) Marselos, M.; Dutton, G.; Hanninen, O. (Dept. Physiology, Univ. Kuopio, SF-70101 Kuopio 10, Finland). *Biochem. Pharmacol.* 24(20):1855-1858; 1975.

The effect of p.o. administration of D-glucaro-1, 4-lactone (glucarolactone) both on β-glucuronidase activity of male Wistar/AF/Han/Mol/(Han 67) rat intestinal contents (at physiologic pH) and on the biologic activity of glucuronidogenic drugs excreted in the bile or urine was investigated. In addition, inhibition by glucarolactone on β-glucuronidase activity from intestinal mucosa and luminal contents was examined *in vitro* (at physiologic pH). Depression of locomotor activity caused by phenobarbital (80 mg/kg, i.p.) or progesterone (160 mg/kg, i.p.) was shortened in rats pretreated with glucarolactone (1.2 g/kg, p.o.), which had no effect when given alone. The duration of the zoxazolamine paralysis (75 mg/kg, i.p.) was not affected, however, by the presence of glucarolactone. After p.o. administration of glucarolactone, β-glucuronidase was greatly inhibited within 6 hr when measured in luminal contents through the intestinal tract at pH values of 6.5, 7.8, and 7.0, which were those found to exist in the jejunum, the ileum, and the colon, resp. Glucarolactone itself, added *in vitro*, inhibited β-glucuronidase from intestinal epithelial cells and luminal contents. The results suggest that inhibition by glucarolactone of the intestinal bacterial β-glucuronidase could enhance the elimination of substances excreted in the bile as D-glucuronic acid conjugates. This is probably mediated by suppressing the enterohepatic circulation of the pharmacologically active aglycones.

0125 CHANGES IN ADENYLATE ENERGY CHARGE OF THE LIVER AFTER AN ORAL GLUCOSE LOAD.

(Eng.) Kimura, K.; Kamiyama, Y.; Ozawa, K.; Honjo, I. (Kyoto Univ. Faculty Medicine, Sakyo-ku, Kyoto, Japan). *Gastroenterology* 70(5):665-668; 1976.

Changes in the adenine nucleotide metabolism after an oral glucose load were studied in the livers of normal and alloxan-induced (7.0 mg/100 g body weight) diabetic Wistar rats. In the oral glucose tolerance test, 6 ml/kg body weight of 50% glucose were administered intragastrically after a 15-hr fast. Changes in the energy charge were positively correlated with those in the blood glucose and plasma immunoreactive insulin levels. One hour after an oral glucose load when the plasma immunoreactive insulin levels increased maximally, the energy charge increased maximally from 0.846 to 0.867 ($p<0.001$). The increase in the energy charge was accompanied by a concomitant decrease in the ADP levels ($p<0.05$). The respiratory control ratio, state 3 respiration/U of cytochrome a(+a_3), and DNP-induced ATPase activity/U of cytochrome a(+a_3) increased significantly. The adenylate kinase and pyruvate kinase activities in the liver remained unchanged. The energy charge in the liver of alloxan-diabetic rats did not increase significantly after an oral glucose load when compared to saline-treated controls. An increase in the energy charge of the liver may be attributable to the more rapid flux of intermediary metabolism in the enhanced ADP-phosphorylating reactions by mitochondria, owing to an elevated level of insulin available to the hepatic cells.

0126 INHIBITION BY SULFOBROMOPHTHALEIN OF MITOCHONDRIAL TRANSLOCATION OF ANIONS AND ADENINE NUCLEOTIDES: EFFECTS UPON LIVER ADENOSINE TRIPHOSPHATE AND POSSIBLE CORRELATION WITH INHIBITION OF BILE FLOW IN THE RAT.

(Eng.) Laperche, Y.; Oudea, P. (Laboratoire de Pathologie Cellulaire Hepatique, E.R.A. 334, C.N.R.S., U.E.R. de Medecine, 1, rue Gaston Veil, 44035 Nantes Cedex, France). *J. Pharmacol. Exp. Ther.* 197(1):235-244; 1976.

The effects of BSP on male rat (Sprague-Dawley CD strain) liver mitochondria *in vitro*, their extent *in vivo*, and their possible correlation with inhibition of bile flow and BSP secretion into bile were studied. Unconjugated BSP inhibited state III respiration of rat liver mitochondria. It competitively inhibited the translocation into mitochondria of citrate, malate, phosphate, and ADP, as

LIBRARY U. OF F.

studied by the inhibitor stop method. Double-beam spectrophotometry strongly suggested that glutamate translocation was similarly inhibited. After perfusion of 65 µmole/hr/100 g for 90 min, bile flow was inhibited by 82%, and liver ATP fell by 60%. The amount of mitochondrial BSP could be computed from the amount of $[^{35}S]$BSP still bound to mitochondria that were prepared at the end of such experiments; the amount of BSP lost during the isolation procedure was estimated from parallel experiments following binding of BSP *in vitro*. Comparison of the kinetic constants of mitochondrial transport and of their inhibition by BSP, on the one hand, and of liver concentrations of substrates and BSP, on the other, leads to the conclusion that a strong inhibition of transports, mainly of phosphate, occurs *in vivo* and is responsible for the observed decrease of ATP levels. The latter is likely to be at least partially responsible for the concomitant decrease in bile flow.

0127 HEPATIC GLUTATHIONE DEPLETION AND IMPAIRED BROMOSULPHTHALEIN CLEARANCE EARLY AFTER PARACETAMOL OVERDOSE IN MAN AND THE RAT.

(Eng.) Davis, M.; Ideo, G.; Harrison, N. G.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5 8RX, England). *Clin. Sci. Mol. Med.* 49(5):495-502; 1975.

The plasma kinetics of BSP was studied in four patients and Wistar rats following paracetamol overdose and in normal subjects after therapeutic doses. Plasma clearance of BSP was impaired in patients within 8 hr, and in rats within 2 hr of paracetamol overdose (30-40 g and 13.2 nmol/kg, resp.), before biochemical signs of liver damage had appeared. Paracetamol and BSP competed for uptake into the liver and excretion into the bile. Impaired hepatic uptake of BSP was also demonstrated in man at doses of the drug within the therapeutic range (0.3 mmol/kg). In the patients, a smaller proportion of BSP was retained in the plasma as the glutathione conjugate after an overdose than after therapeutic doses. This effect could be reproduced in the rat and was shown to be due to depletion of hepatic glutathione and to impairment in the activity of glutathione-*S*-aryl transferase. These studies provide further evidence that depletion of hepatic glutathione occurs after paracetamol overdose in man and in the experimental animal, allowing the subsequent accumulation and binding of a toxic metabolite of the drug within liver cells. Impaired enzymic conjugation of the toxic metabolite with hepatic-reduced glutathione may also be important in this situation.

0128 LYSOLECITHIN-MEDIATED INFLAMMATORY REACTION IN RABBIT GALLBLADDER: PERMEABILITY INCREASE AND ENZYME LIBERATION.

(Eng.) Sjodahl, R.; Tagesson, C.; Wetterfors, J. (Univ. Hosp., Linkoping, Sweden). *Acta Chir. Scand.* 141(5):403-408; 1975.

Inflammatory changes mediated by lysolecithin were quantitated *in vitro* by studying permeability across the gallbladder wall and lysosomal integrity of four domestic male rabbits. Wall permeability changes were measured as changes in the transmural passage of radioactively labeled hippuran and biligraphin. Acid phosphatase release from wall to lumen was determined using 10 mM *p*-nitrophenylphosphate as substrate. When 6-20 mg/ml lysolecithin were instilled into the gallbladders, dose-dependent increases in permeability and enzyme release occurred. No effects as compared with controls were seen when 2 mg/ml were instilled. Lysolecithin-treated gallbladders showed morphological signs of inflammation as opposed to untreated gallbladders. These data reported are consistent with observations that lysolecithin may cause inflammatory lesions to the gallbladder wall. The authors conclude that this model may prove useful in examining the effects of aggressive and protective agents upon the gallbladder mucous membrane.

0129 SERUM TRANSAMINASE LEVELS AFTER EXPERIMENTAL PARACETAMOL-INDUCED HEPATIC NECROSIS.

(Eng.) Dixon, M. F.; Fulker, M. J.; Walker, B. E.; Kelleher, J.; Losowsky, M. S. (Dept. Pathology, Univ. Leeds, Leeds, England). *Gut* 16(10):800-807; 1975.

The relation between serum transaminase levels and the extent of paracetamol-induced liver necrosis was investigated in Tuck-Wistar rats. Three methods of histological quantitation were used to assess the degree of necrosis: arbitrary grading, point counting, and the image-analysis computer (500,000 picture points/field). Highly significant correlations were obtained from all methods, and all were found to be reproducible. A close correlation was found between the extent of hepatic necrosis and the serum aspartate aminotransferase and alanine aminotransferase 24 hr after a large dose (4 g/kg) of paracetamol. The mean grade of necrosis correlated reasonably well with the serum enzyme levels in the recovery phase at 36 and 72 hr, although the transaminase level for a given degree of necrosis was considerably lower at 72 hr than at 24 hr. These findings suggest that serum transaminase levels give a reliable indication of the severity of hepatic necrosis (even in the recovery phase) if the time of ingestion of paracetamol is taken into account.

0130 ACUTE, SUBACUTE, AND RESIDUAL EFFECTS OF POLYCHLORINATED BIPHENYL (PCB) IN RATS. II. PATHOLOGY AND ELECTRON MICROSCOPY OF LIVER AND SERUM ENZYME STUDY.

(Eng.) Kasza, L.; Weinberger, M. A.; Carter, C.; Hinton, D. E.; Trump, B. F.; Brouwer, E. A. (Division Pathology, Food and Drug Admin., 200 C St., S.W., Washington, DC 20204). *J. Toxicol. Environ. Health* 1(5):689-703; 1976.

A study was undertaken to determine the residual effects of a polychlorinated biphenyl (Aroclor 1254) at dietary concentrations of 0, 5, 50, and 500 ppm in the diet of male rats. The animals were treated for 4 weeks (acute and subacute phase), then observed for periods of up to 50 weeks following termination of exposure (residual phase). The most significant histopathologic alteration was fatty degenerative change in the liver, which was most marked at 9 weeks. Forty-six weeks after exposure, over 50% of the rats fed 500 ppm still demonstrated fatty degenerative changes. Electron microscopy revealed marked increased in lipid vacuoles and smooth endoplasmic reticulum (SER), with a concomitant decrease in rough endoplasmic reticulum (RER) profiles in the animals receiving 50-500 ppm for 4 weeks. Thirty-seven weeks following the exposure period, rats dosed with 50 ppm showed partial recovery toward control morphology (less lipid, less SER, more RER), while those receiving 500 ppm did not. Persistent morphologic alterations included an increase in SER and medium-density lipid material within cisternae of SER, Golgi, and Golgi-condensing vesicles, as well as a decrease in parallel arrays of RER. The persistence of ultrastructural alteration throughout the 46-week residual phase emphasizes the long-lasting effects of 4 weeks of exposure to polychlorinated biphenyl, and that even short-term administration may modify the metabolism of drugs, hormones, and pesticides for long periods of time.

0131 STUDIES ON THE HEPATOTOXICITY OF Aminita phalloides IN THE RAT: 1. LIVER CELL VACUOLATION.

(Eng.) Baccino, F. M.; Cantino, D.; Zuretti, M. F. (Istituto di Patologia Generale dell'Universita, Corso Raffaello 30, I-10125 Torino, Italy). *Exp. Mol. Pathol.* 24(2):159-175; 1976.

The pathogenesis of the hepatocytic vacuolation by *Amanita phalloides* was studied in male Wistar rats, and the time sequence of selected morphological, histochemical, and biochemical changes of hepatocytes and their lysosomes were correlated during the development of the damage. Rats were given mushroom extract (0.5 ml/100 g, i.p.), and light, electron, and fluoresence microscopy and enzyme histochemical techniques were used to study liver damage. The first changes were detected at the level of the hepatocytic plasmalemma, both histochemically (ATPase and 5'-nucleotidase) and ultrastructurally. At the sinusoidal surface, the early development of multiple invaginations, giving rise to cytoplasmic vacuoles, was later followed by the complete disappearance of microvilli. Moreover, microfilaments formed prominent clusters juxtaposed to the inner surface of the plasma membrane at both the sinusoidal and biliary poles. Cytoplasmic vacuoles developed in hepatocytes early after poisoning due to the progressive overloading of cells with plasma proteins and blood cells. Both blood-derived materials finally flooded hepatocytes. Heterophagic and autophagic processes contributed cytoplasmic organelles and glycogen to be segregated into the vacuoles, which thereby acquired an ambiphagosomal character. Autophagosomes were also increased. A large proportion of vacuoles, except for the largest ones in the late stages of the poisoning, acquired acid phosphatase activity; this presumably derived from preexisting lysosomes, which strongly decreased in number. Many vacuoles also contained diastase-resistant, PAS-positive material. Thus, suitable i.p. doses of *A. phalloides* brings about an extensive cytoplasmic vacuolation of rat liver parenchymal cells, followed by cell death with interstitial hemorrhage.

0132 EFFECTS OF FASTING AND REFEEDING ON SECRETORY GRANULES OF THE MOUSE GALLBLADDER EPITHELIUM: A QUANTITATIVE ELECTRON MICROSCOPIC STUDY.

(Eng.) Wahlin, T.; Bloom, G. D.; Carlsoo, B.; Rhodin, L. (Dept. Histology, Univ. Umea, S-901 87 Umea, Sweden). *Gastroenterology* 70(3):353-358; 1976.

Gallbladder epithelial cells of 25 male C57BL mice were studied by electron microscopy during fasting and refeeding to determine if variations in food intake are reflected in epithelial cell secretory activity. Morphometric data were obtained from randomly selected epithelial cells of normal, starved (12, 24, and 48 hr), and refed (12 hr) mice. Deprivation of food significantly diminished the volume density of the mucinous secretory granules by about 70% after 48 hr of fasting. Upon refeeding, this secretory granule parameter increased significantly (approximately 2.5 times). Stereological measurements were also performed on nuclei, mitochondria, and lysosomes, but no major morphometric changes were observed in these organelles. The findings suggest that a basal secretion of mucin granules occurs in the mouse gallbladder, irrespective of the animals' nutritional state and that this discharge during starvation exceeds the formation of new granule material. The mucous secretory activity of the mouse gallbladder is influenced by the nutritional state of the animals and the qualitative composition of the diet.

0133 ALTERED BILE ACID METABOLISM IN VEGETARIANS.

(Eng.) Hepner, G. W. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA 17033). *Am. J. Dig. Dis.* 20(10):935-940; 1975.

To assess the effect of meat on bile acid metabolism, bile acid kinetics were compared in a group of healthy vegetarians (10) and a matched group of healthy control subjects. The daily fractional turnover rate of cholic acid and the deoxycholic acid pool size were significantly smaller in the vegetarians than in the controls. The data suggest that enterohepatic conservation of cholic acid is more efficient in vegetarians than in control subjects resulting in decreased deoxycholic acid input in vegetarian subjects. It is suggested that meat in the diet may lead to an oncogenic effect by increasing the deoxycholic acid pool size and input into the enterohepatic circulation.

0134 CORRELATION OF PLASMA LYSOSOMAL ENZYME LEVELS WITH HEPATIC RETICULOENDOTHELIAL FUNCTION AFTER TRAUMA.

(Eng.) Loegering, D. J.; Kaplan, J. E.; Saba, T. M. (Albany Medical Coll., Albany, NY 12208). *Proc. Soc. Exp. Biol. Med.* 152(1):42-46; 1976.

Plasma lysosomal enzyme levels and hepatic phagocytosis were determined following Noble-Collip drum trauma in male Sprague-Dawley rats. Circulating cathepsin and acid phosphatase activity increased

LIBRARY U. OF I. URBANA-CHAMPAIGN

after sublethal trauma (300 revolutions), reaching maximal levels at 1-3 hr and returning to pretrauma levels 24 hr after trauma. Hepatic phagocytosis was decreased maximally at 1 hr and recovered to control levels at 24 hr after sublethal trauma. Increasing trauma intensity (100-500 revolutions) resulted in a progressive failure in hepatic Kupffer cell phagocytosis and a progressive increase in plasma lysosomal enzyme levels when tested 60 min post-trauma. A significant inverse correlation was found between the plasma lysosomal enzyme levels and Kupffer cell phagocytosis after trauma.

0168 A STUDY OF INTRALUMINAL PEPTIDE HYDROLASE ACTIVITY IN THE RAT.

(Eng.) Silk, D. B. A.; Kim, Y. S. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Clin. Sci. Mol. Med.* 49(5):523-526; 1975.

A potential source of luminal peptide hydrolase activity was investigated and the hydrolysis of two further peptides by jejunal and ileal contents was compared in male Wistar rats. Uncentrifuged and centrifuged rat intestinal contents were assayed for peptide hydrolase activity with glycyl-L-phenylalanine (Gly-Phe) and L-phenylalanyl-glycine (Phe-Gly) as substrates in the absence and presence of the intestinal cytosol peptide hydrolase inhibitor *p*-hydroxymercuribenzoate (PHMP, 500 μM). Jejunal contents hydrolyzed Gly-Phe faster than Phe-Gly. Conversely, ileal contents hydrolyzed Phe-Gly faster than Gly-Phe. PHMP markedly inhibited jejunal peptide hydrolase activity. There was ten times as much PHMB-resistant activity towards both dipeptides in ileal contents as in jejunal contents. Most of the luminal enzyme activity (89-96%) was present in the supernatants after centrifugation, indicating that the luminal enzymes exist in the soluble form. Although the presence of soluble bacterial enzymes cannot be excluded, peptide hydrolase enzymes in jejunal contents have the characteristics of mucosal cytosol enzymes, whereas enzymes in ileal contents have the characteristics of mucosal brush border as well as cytosol enzymes.

0169 INTESTINAL DISACCHARIDASE AND PEROXIDASE ACTIVITIES IN PARENTERALLY NOURISHED RATS.

(Eng.) Castro, C. A.; Copeland, E. M.; Dudrick, S. J.; Johnson, L. R. (Univ. Texas Medical Sch., Houston, TX 77025). *J. Nutr.* 105(6):776-781; 1975.

The importance of the presence of food in the gastrointestinal tract in maintaining normal enzyme activity in the small intestine was investigated in male Sprague-Dawley rats that were kept from eating for as long as 2 weeks. During this time animals were sustained on a nutrient solution administered i.v. Enzyme activity and small bowel mass in these animals and similar parameters in rats administered the same solution p.o. were compared with control groups fed an essentially isoenergetic diet of stock rat food and water. Disaccharidase and peroxidase levels in mucosal scrapings expressed as activity/mg protein, activity/intestine, and activity/100 g body weight were significantly reduced in nourished rats but not in rats receiving the nutrient solution p.o. The activities of maltase, sucrase, trehalase, palatinase, and lactase, as well as peroxidase, were significantly reduced in parenterally nourished rats as compared with controls. In addition, parenteral feeding was accompanied by a significant reduction in the small bowel weight:body weight ratio as compared with that of rats fed the stock diet or nutrient solution p.o. The results support the conclusion that normal activity of intestinal enzymes spatially distributed with regard to depth within the mucosa depends on the presence of food in the gastrointestinal tract and cannot be maintained at normal levels by total i.v. nutrition.

0170 METABOLIC HETEROGENEITY OF LECITHINS IN INTESTINE.

(Eng.) Akino, T.; Ohno, K. (Sapporo Medical Coll., Sapporo, Japan). *Tohoku J. Exp. Med.* 116:385-389; 1975.

The incorporation of [2-^{3}H]-glycerol and lysolecithin labeled with [2-^{3}H]-glycerol into lecithin and its subspecies was investigated into epithelial and muscular layers of rat small intestine. The labeled compounds were administered either by intraduodenal injection or injection into femoral vein. The incorporation of glycerol into lecithin was distinctly higher in the epithelial layer than in the muscular layer 5 and 20 min following injection by both routes, but the incorporation of lysolecithin into lecithin showed no marked differences between both layers. Among lecithin species, dienoic and monoenoic species were highly labeled with the injection of labeled glycerol, and dienoic as well as tetraenoic species were markedly labeled with the injection of labeled lysolecithin. However, no significant difference was found in the incorporation pattern of any labeled compound into lecithin between both layers and between both administration routes.

0171 EFFECT OF Klebsiella pneumoniae ENTEROTOXIN ON INTESTINAL TRANSPORT IN THE RAT.

(Eng.) Klipstein, F. A.; Horowitz, I. R.; Engert, R. F.; Schenk, E. A. (Tropical Malabsorption Unit, Univ. Rochester, NY 14642). *J. Clin. Invest.* 56(4):799-807; 1975.

The effects on intestinal transport (net fluid and electrolyte secretion) of either a semipurified preparation of enterotoxin elaborated by *Klebsiella pneumoniae* serotype 5 or similarly prepared control material were tested by marker perfusion studies in the jejunum and ileum of Sprague-Dawley rats. Enterotoxin (2 mg/ml) produced net secretion of water, Na, and Cl in both jejunal and ileal segments; HCO_3 transport was not affected. Net secretion was evident within 30 min after introduction of the toxin and was maximal after 90 min. The addition of 56 mM glucose to the enterotoxin-containing perfusion fluid resulted in reversal of water and Na transport to net absorption in both intestinal segments. The enterotoxin also produced a significant depression of xylose absorption in both the jejunum and ileum but did not affect the absorption of either glucose of L-leucine. Intestinal structure was not altered after perfusion of the toxin but instillation of approximately one-fourth of the total perfusion dose into a ligated jejunal loop for 18 hr produced fluid secretion and structural abnormalities. These observations confirm that other species of coliform bacteria in addition to *Escherichia coli* are capable of elaborating an enterotoxin. The authors suggest that chronic exposure of the intestinal mucosa to the enterotoxin elaborated by these bacteria may be a factor in the pathogenesis of intestinal abnormalities in cases of acute undifferentiated diarrhea or diarrhea associated with either acute gastroenteritis or chronic malnutrition.

SECRETION AND METABOLISM

GENERAL

0180 EFFECTS OF POTASSIUM IONS AND SODIUM IONS ON MEMBRANE POTENTIAL OF EPITHELIAL CELLS IN RAT DUODENUM. (Eng.) Okada, Y.; Sato, T.; Inouye, A. (Kyoto Univ. Sch. Medicine, Kyoto, 606, Japan). *Biochim. Biophys. Acta* 413(1):104-115; 1975.

The effect of K^+ and Na^+ concentration changes on the potential profiles of rat duodenum membrane was analyzed. Mucosal and serosal membrane potentials (V_m and V_s) of epithelial cells in the duodenum were recorded together with the transmural potential differences (PD_t). The value of V_m in the duodenum at 37 C was approximately -53 mV. When Cl^- in the mucosal medium was partially replaced with SO_4^{2-} at fixed mucosal Na^+ and K^+ concentrations ($[Na^+]_m$ and $[K^+]_m$), the membrane potential was scarcely affected in the steady state several minutes after replacement, whereas marked changes in the potential were observed with varying $[K^+]_m$ or $[Na^+]_m$. As the mucosal K^+ concentration increased at constant $[Na^+]_m$, V_m was gradually decreased (depolarization), together with the increase in PD_t. At constant $[K^+]_m$, an increase in $[Na^+]_m$ also caused the decrease of V_m for the lower $[K^+]_m$ region, whereas V_m was not affected by such changes in $[Na^+]_m$ in the range of $[K^+]_m$ higher than approximately 60 mM. The values of P_{Na}/P_K were obtained from the modified Goldman equation under an appropriate assumption. The ratio of the permeability coefficients markedly increased from zero to approximately 0.07 with a decrease in $[K^+]_m$. The authors attribute their elevated values of membrane potential (compared to previous experiments with rat, hamster, rabbit, and tortoise intestine) to the preservation of the intact normal blood supply until the tissue was mounted.

0181 INTERSTITIAL FLUID PRESSURE AND ALKALINE GASTRIC SECRETION. (Eng.) Altamirano, M.; Requena, M.; Perez, T. C. (Sch. Medicine, Univ. Puerto Rico, San Juan, PR). *Am. J. Physiol.* 229(5):1421-1426; 1975.

LIBRARY U. OF F.

The interstitial fluid pressure (IFP) of the submucosa of the gastric fundus was monitored by means of Guyton's capsules in dogs anesthetized with pentobarbital to determine whether hydraulic gradients generated by changes in the IFP cause secretion of interstitial fluid (IF). The intracapsular pressure (ICP) was measured during secretion produced by: a) hypertonic solutions placed inside the stomach, b) arterial hypertension (200 mm Hg) applied during intra-arterial infusion of histamine, and c) intra-arterial infusion of acetylcholine. The first procedure did not modify the ICP. The mean ICP increased, mostly due to augmented capillary filtration, whenever interstitial fluid appeared in the gastric lumen during hypertension plus histamine. The hydraulic coefficient measured in these experiments was at least four orders of magnitude larger than the respective osmotic coefficient. The action of acetylcholine was complex; large doses enlarged the net capillary filtration, but small doses increased the mean ICP by muscle stimulation only. The authors suggest that contraction of the muscularis mucosae may be the most important mechanism underlying bulk flow of interstitial fluid in physiological conditions. It is concluded that hydraulic gradients across the epithelium might account for the "secretion" of "alkaline" juice.

0182 ADRENERGIC MECHANISMS IN CANINE GASTRIC CIRCULATION. (Eng.) Zinner, M. J.; Kerr, J. C.; Reynolds, D. G. (Walter Reed Army Medical Center, Washington, DC 20012). *Am. J. Physiol.* 229(4):977-982; 1975.

The effects of adrenergic amines administered by direct intra-arterial injections over a logarithmic dose range on the stimulation and blockade of gastric circulation were studied in 10 anesthetized dogs. Blood flow through the right and left gastric artery was measured electromagnetically. Norepinephrine and isoproterenol (both at 10^{-3}-10^{0} μg/kg) were injected intra-arterially and i.v. before and after alpha- and beta-adrenergic blockade. Isoproterenol caused vasodilation of both right and left gastric circulations, this effect was attenuated by beta blockade. Epinephrine and norepinephrine induced constriction followed by dilation in both circulations. The constrictor components were attenuated or abolished by alpha-adrenergic blockade (induced by 1.5 mg/kg phenoxybenzamine hydrochloride), and the dilator components were attenuated by beta-adrenergic blockade (induced by 0.5 mg/kg i.v. propranolol). The left gastric circulation had a greater vasodilator response to each adrenergic amine than did the right gastric circulation to the same dose of amine. These data support the classical concepts that epinephrine and norepinephrine are "mixed" adrenergic agonists while isoproterenol is a "pure" beta-adrenergic agonist. These data further suggest that there is an unequal distribution of beta-adrenergic receptors in the left gastric vasculature.

0183 EFFECT OF SECRETIN AND CHOLECYSTOKININ ON SMALL INTESTINAL BLOOD FLOW DISTRIBUTION. (Eng.) Fara, J. W.; Madden, K. S. (Health Sci. Center, State Univ. New York, Stony Brook, NY 11794). *Am. J. Physiol.* 229(5):1365-1370; 1975.

The relative blood flow distribution to the mucosa, submucosa, and muscularis of the small intestine of fasted, anesthetized cats was determined using radioactive microspheres (^{85}Sr) during control periods and periods of increased superior mesenteric blood flow. I.v. infusions of secretin (2-10.7 U/kg·hr), cholecystokinin (CCK, 0.5-6.5 U/kg·hr), or isoproterenol (2.5-5.5 μg/min) increased superior mesenteri blood flow by 15-85%. The microspheres, 15 μm in diameter, were injected into the superior mesenteric artery and shortly thereafter intestinal segments were removed and dissected into mucosal, submucosal, and muscularis fractions. During secretin-induced mesenteric vasodilatation there was a significant redistribution of blood away from the jejunal mucosa to the submucosa. During CCK and isoproterenol infusions there were significant increases in mucosal and decreases in submucosal blood flow. No significant changes were observed in muscularis flow. There was no apparent relation between the percent increase in submucosal blood flow and the relative blood flow distribution changes observed. The results indicate that while secretin, CCK, and isoproterenol increase superior mesenteric blood flow, they also affect blood flow distribution within the mucosa and submucosa.

DIAGNOSTIC PROCEDURES

0189 MEASUREMENT OF FAT ABSORPTION UTILIZING ^{131}IODINE-TRIOLEIN AND NONABSORBABLE RADIOACTIVE MARKERS. (Eng.) Shafer, R. B.; Onstad, G. R. (Veterans Admin. Hosp., Minneapolis, MN 55417). *Am. J. Med. Sci.* 269(3):327-331; 1975.

A double-isotope technique utilizing ^{131}I-triolein and a nonabsorbable marker, ^{131}barium sulfate (^{131}Ba) was employed for the quantitative determination of fecal fat in man. The ratios of radioactivity of ^{131}Ba/^{131}I in a prepared capsule and that found in a random "grab" stool specimen after oral administration of the capsule were compared to determine the amount of fat absorbed. In an initial 36 patients, this technique accurately separated normal from abnormal fat absorption as determined by the usual methods of quantitative fecal fat measurement. Results in an additional 102 patients and in 26 normal subjects accurately reflected their clinical states. In addition, *in vitro* studies demonstrated more complete recovery of added lipid (99%) by radioactive techniques than by chemical analysis (86%). The authors conclude that the double-label technique seems to be more accurate than usual quantitative fecal fat determinations, and that it greatly simplifies the measurement of fat absorption in man by eliminating the need for special diets, quantitative stool collections, and chemical analysis of stool.

0190 INTRAVENOUS CHOLANGIOGRAPHY: OPTIMUM DOSAGE AND METHODOLOGY. (Eng.) Scholz, F. J.; Johnston, D. O.; Wise, R. W. (Peter Bent Brigham Hosp., Boston, MA). *Radiology* 114(2):513-518; 1975.

The effect of varying doses of methylglucamine iodipamide (Cholografin) on visualization of the cholangiogram and toxicity was investigated in 442 patients. Cholangiography was performed using four dosage regimens of Cholografin: a single injection, 10.4 g in 20 ml for 10 min (150 subjects); a single dilute dose, 10.4 g in 40 ml for 30 min (76 subjects); a very dilute single dose, 10.4 g in 100 ml for 30 min (71 subjects); or one dilute double dose, 20.8 g in 80 ml for 30 min (145 subjects). There was no significant difference in the unsuccessful examination rate among the four dosage groups. Opacification was maximum with the double-dose infusion (58.6% good visualization); however, visualization was better with the single-dose injection (52%) than with the two single-dose infusions (41.5%). The double-dose infusion produced more dermal reactions than either the single-dose injection or the single-dose infusion. In 149 of the patients given a single dose, the SGOT levels were determined following cholangiography. The incidence of SGOT elevation with the double-dose infusion was twice that with the other methods. It is concluded that the standard method of administering Cholografin, injecting 20 ml at a steady rate over a 10-min period, is the best technique, despite slightly lower opacification.

0191 COMPLICATIONS OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP): A STUDY OF 10,000 CASES. (Eng.) Bilbao, M. K.; Dotter, C. T.; Lee, T. G.; Katon, R. M. (Univ. Oregon Health Sci. Center, Portland, OR). *Gastroenterology* 70(3):314-320; 1976.

Inquiries were mailed to 402 owners of the cannulating duodenoscope requesting information concerning complications that occurred during endoscopic retrograde cholangiopancreatography (ERCP) examinations. Fifty-five percent of the owners responded and of these, 25% had not yet attempted any ERCP's. Specific data on complications were analyzed for 8,681 ERCP's of the 10,435 cases reported. The overall cannulation success rate was 70%. The overall complication rate was 3%, and the overall death rate was 0.2%. Clinically evident acute pancreatitis developing within 24 hr was the commonest complication, occurring in 1% of the cases. Suggestions to decrease this complication include: limit pancreatic injection to a slow dribble, fluoroscopically monitored, stopping as soon as branch ducts are seen; wait for pancreatic emptying before reinjecting; limit the number of injections; check in each case for a urogram; and where a urogram is noted, allow the patient only parenteral feeding overnight. Cholangitic sepsis was reported in 0.8% of the cases. Prompt surgical relief of obstruction (24-48 hr) was the most important preventive measure. Pancreatic sepsis/pseudocyst abscess was reported in 0.3%. Suggestions for preventing this complication include antibiotics, underinjection of ducts, decompression operation, and aseptic techniques. Instrumental injury occurred in 0.2%, usually in patients whose anatomy was abnormal or confusing. Drug reactions were reported in 0.6% of the cases, diazepam being the most common offender. Examination failure occurred in 30% of the attempted ERCP's. Promising techniques for preventing complications in ERCP studies include monometric injection monitoring, prophylactic antibiotic use, and special training programs in ERCP.

0192 HYPERAMYLASAEMIA AFTER DUODENOSCOPY AND RETROGRADE CHOLANGIOPANCREATOGRAPHY. (Eng.) Skude, G.; Wehlin, L.; Maruyama, T.; Ariyama, J. (Univ. Lund, Malmo General Hosp., Malmo, Sweden). *Gut* 17(2):127-132; 1976.

The salivary and pancreatic isoamylases of serum were determined separately, before and after 234 duodenoscopy and retrograde cholangiopancreatography examinations, in 219 patients with suspected duodenal, pancreatic, or hepatic disease. Successful pancreatic opacification was associated with pathologically high pancreatic serum amylase activities in 60% of the cases. Extensive opacification was associated with large increases of pancreatic serum isoamylases; the maximal rise recorded was 40 times the initial value. In spite of these striking chemical events only two patients developed clinical acute pancreatitis. There were some variations in pancreatic opacification and in the elevation of pancreatic serum amylase, which seemed to depend upon the particular contrast material used. A rise of the salivary serum isoamylases caused pathologically high total serum amylase activities in 7% of the cases. High levels of pancreatic serum isoamylase activity before the time of examination did

LIBRARY U. OF I.

not result in any different pattern of hyperamylasemia.

0193 AN EVALUATION OF ECHOGRAPHY IN THE DIAGNOSIS OF PANCREATIC DISEASE. (Eng.)

Fontana, G.; Bolondi, L.; Conti, M.; Plicchi, G.; Gullo, L.; Caletti, G. C.; Labo, G. (Medical Clinic II, Univ. Bologna, Bologna, Italy). *Gut* 17(3):228-234; 1976.

The efficacy of echography as a tool in the diagnosis of pancreatic disease was studied in 52 patients, and the results were compared with those from other diagnostic techniques. In 65.7% of the 42 chronic pancreatitis patients, and in all 7 cases of carcinoma of the pancreas, echography provided evidence of pancreatic abnormality but in no case could an unambiguous diagnosis of the disease be made. However, in all three cases of pancreatic cyst, echography gave precise and unequivocal diagnostic information. There was good agreement between the echographic picture and surgical findings. Cholangiography and duodenography indicated duodenal and choledochal compression in a high proportion of cases in which echography revealed enlargement of the head of the pancreas. It is concluded that echography is a simple, safe, and valuable addition to the techniques available for studying the pancreas.

0194 LIMITATIONS OF ULTRACENTRIFUGATION AND IN VIVO DIALYSIS AS METHODS OF STOOL ANALYSIS. (Eng.)

Owens, C. W. I.; Padovan, W. (Univ. Coll. Hosp. Medical School, London, England). *Gut* 17(1):68-74; 1976.

Human fecal analyses were made to validate high speed centrifugation and *in vivo* dialysis as methods of sampling extracellular stool fluid. Feces, free from urine, collected from nine healthy males were used to assess the difference between ultracentrifugate and dialysate (the U-D difference). Amino acid analysis by cation exchange chromatography demonstrated highly significant U-D differences for some amino acids, but not for others, e.g., phenylalanine, citrulline, isoleucine, valine, alanine, and tyrosine were present in higher concentrations after handling and centrifuging. Sonication of diluted stool exaggerated the U-D differences for various amino acids; dilution, itself, was not responsible. There were no significant differences between the ionic concentrations of potassium, sodium, or chloride in centrifugate and dialysate. Sonication did not increase the potassium concentration significantly, explained by a lack of reproducibility in the analytical method and the similarity of the intra- and extracellular concentrations. The U-D difference was not explained by the diffusion characteristics of the dialysis bag. Low speed (6,000 x *g*) supernatants had slightly higher amino acid concentrations than did their 26,000 x *g* or 40,000 x *g* counterparts. The higher values were attributed to cloudy supernatants containing cells that subsequently ruptured. The main differences were seen in glutamate and alanine. Incubation under oxygen or air, as opposed to nitrogen, caused release of certain amino acids. It was concluded that both methods of stool water sampling have limitations and that aerobically prepared ultracentrifugate is probably not equivalent to stool water. Under suitable conditions, *in vivo* dialysis provides the most convenient and accurate method of stool water sampling and the closest approximation to extracellular fluid, providing the feces remain in the descending colon or rectum for at least 2 hr. If this is not possible, then centrifugation is an alternative providing the stool is kept under nitrogen, stored for a minimum period (preferably at 4 C or room temperature), and centrifuged at 40,000 x *g*.

0195 LOSS OF COLONIC HAUSTRATION IN PROGRESSIVE SYSTEMIC SCLEROSIS. (Eng.)

Martel, W.; Chang, S. F.; Abell, M. R. (Univ. Michigan Medical Center, Ann Arbor, MI 48104). *Am. J. Roentgenol.* 126(4):704-713; 1976.

Roentgenologic and microscopic findings in the colon of 20 patients are reported to investigate the association between loss of colonic haustration and systemic sclerosis. The cases were classified into four groups according to the predominant roentgenologic abnormality: ahaustral, relatively ahaustral, sacculation (characteristic of scleroderma), or normal. Of the 20 patients, 6 had severe loss of colonic haustration on barium enema examination, 12 had varying degrees of haustration loss or colonic sacculation, and 2 had no colonic abnormality. An increase in colonic length was characteristic and occasionally, there was slight to moderate generalized dilatation. Loss of haustration was most obvious roentgenologically in the transverse and descending portions of the colon. In the eight patients in whom necropsy was performed, the only consistent histologic findings were atrophy and fibrosis of the muscularis propria. These were patchy, variable in severity, and involved both muscular coats. The authors suggest that muscular atrophy and fibrous replacement, characteristics of systemic sclerosis, may cause colonic lengthening and loss of haustration. It is stressed that this appearance must not be confused with other conditions, particularly chronic ulcerative colitis.

GASTROINTESTINAL DISEASES

ESOPHAGUS

0233 THE COLUMNAR EPITHELIAL-LINED LOWER ESOPHAGUS AND ITS ASSOCIATION WITH ADENOCARCINOMA OF THE ESOPHAGUS. (Eng.) Cho, K. J.; Hunter, T. B.; Whitehouse, W. M. (Wayne County General Hosp., Eloise, MI 48132). *Radiology* 115(3):563-568; 1975.

The case reports of four patients with columnar epithelial-lined lower esophagus are presented. The condition was complicated by esophagitis (one patient, an 18-yr-old man with cystic fibrosis), ulceration (one patient, a 54-yr-old woman with esophageal adenocarcinoma), perforation (one patient, a 31-yr-old man), and adenocarcinoma of the esophagus (two patients, the 54-yr-old and a 62-yr-old woman). When the squamocolumnar junction was involved by peptic esophagitis, the area of mucosal transition appeared as a tapered, strictured segment or a ring-like constriction some distance proximal to the muscular esophagogastric junction. Hiatal incompetence with massive gastroesophageal reflux was evident in one case. A deep penetrating ulcer may occur anywhere along the columnar epithelium, identical to peptic gastric ulceration. The columnar-lined lower esophagus should probably be considered a premalignant condition.

0234 COLUMNAR-LINED LOWER ESOPHAGUS: AN ACQUIRED LESION WITH MALIGNANT PREDISPOSITION. REPORT ON 140 CASES OF BARRETT'S ESOPHAGUS WITH 12 ADENOCARCINOMAS. (Eng.) Naef, A. P.; Savary, M.; Ozello, L. (Yverdon Hosp., 1400 Yverdon, Switzerland). *J. Thorac. Cardiovasc. Surg.* 70(5):826-835; 1975.

Findings on 140 cases of extensive columnar metaplasia of the distal esophagus, 12 of whom had esophageal adenocarcinomas, are reported in an analysis of 1225 cases of reflux esophagitis. All cases of columnar metaplasia were studied by endoscopy, photography, and histologic examination. The columnar heterotropic epithelium tended to ascend from the cardia into the distal esophagus. Photographs demonstrated that peptic ulcerations of the squamous epithelium were progressively replaced by columnar metaplasia during the healing phase of peptic esophagitis. The 12 adenocarcinomas represented an unusually frequent association with extensive columnar metaplasias, suggesting a causal relation between the two pathological conditions. Clinical, endoscopic, and pathological follow-ups for at least 5 yr after fundoplication established that in the postoperative absence of irritating reflux, the topographic distribution of heterotopic columnar epithelium remained unchanged. The most important discovery was that of the possible malignant transformation of heterotopic columnar epithelium into an adenocarcinoma in spite of an efficient antireflux operation, and thus, complete absence of active esophagitis. The authors suggest that repeated esophagoscopic controls and biopsies are an absolute necessity in all cases of extensive columnar metaplasia, even after cure of active reflux esophagitis by fundoplication.

0235 GASTRIC ACID SECRETION AND LOWER-ESOPHAGEAL-SPHINCTER PRESSURE IN RESPONSE TO COFFEE AND CAFFEINE. (Eng.) Cohen, S.; Booth, G. H., Jr. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *N. Engl. J. Med.* 293(18):897-899; 1975.

The dose-response relations of caffeine, regular coffee, and decaffeinated coffee were compared for gastric acid secretion and sphincter pressure in eight normal subjects (21-36 yr-old). Decaffeinated coffee gave a maximal acid response of 16.5 ± 2.6 mEq/hr that was similar to that of regular coffee, 20.9 ± 3.6 mEq/hr, both values being higher than that of caffeine, 8.4 ± 1.3, on a cup-equivalent basis. Sphincter pressure showed minimal changes in response to caffeine, but was significantly increased by both regular and decaffeinated coffee ($p < 0.05$). These data suggest that both regular and decaffeinated coffee are more potent stimulants of gastric acid secretion than caffeine and that clinical recommendations based upon the known gastrointestinal effects of caffeine may bear little relation to the actual observed actions of coffee or decaffeinated coffee.

0264 DISTRIBUTION OF PARIETAL CELLS IN THE ANTRAL MUCOSA OF HUMAN STOMACHS. (Eng.) Tominaga, K. (Tokyo Metropolitan Komagome Hosp., 3-18-22, Honkomagome, Bunkyo-ku, Tokyo, Japan). *Gastroenterology* 69(6):1201-1207; 1975.

The distribution of parietal cells in the antral mucosa was examined in 118 stomachs obtained at necropsy from 72 men and 46 women (all ages) who died from a wide variety of causes, except gastric lesions. The parietal cells appeared in the antrum in 116 cases. The patterns of distribution of parietal cells were divided into four groups. The most frequent pattern (76.3%) was that in which the parietal cells were distributed in all regions of the antrum including just proximal to the gastroduodenal junction. Parietal cells were found most frequently in the area just proximal to the junction in patients aged 20-40 yr and also at 70 yr of age. In 18 of the 118 stomachs, the focal concentration of the parietal cells near the duodenum was greater than the other part of the antrum, reaching more than 50% of the parietal cells of the average fundic gland. The density increased in slight antral gastritis and decreased in cases with moderate to severe antral gastritis. Clustered parietal cells were present in the proximal part of the duodenum in 27 of 118 cases. As parietal cells were also found in the antrum of stomachs of newborns and infants (< 1 yr of age), their presence could not be attributed to metaplasia or dystopia. Thus, the authors consider the parietal cells in the antrum a usual cell component of the pyloric gland.

0265 THE PREVALENCE OF GASTRIC AUTOANTIBODIES IN CHRONIC ALCOHOLICS. (Eng.) Pitchumoni, C. S.; Lopes, J. D.; Glass, G. B. J. (Metropolitan Hosp. Center, 1901 First Ave., New York, NY 10029). *Am. J. Gastroenterol.* 64(3):187-190; 1975.

Alcoholic men and women (150) and nonalcoholic controls (150, age and sex-matched) were evaluated for the presence of parietal cell antibodies (PCA). Blocking and binding intrinsic factor antibodies (IFA) were determined in the PCA-positive sera. The prevalence and age and sex distribution of PCA in the alcoholics and nonalcoholics were identical. In alcoholics over the age of 60 yr, the incidence of PCA although higher than in those of the younger age groups was similar to that in the nonalcoholics of the same age group (in men, 6.3% and 7.3% and in women, 7.5% and 10.0%, resp.). Antral gastritis of moderate or severe degree was the frequent lesion in alcoholics. This form of gastritis was not associated with any significant increase in the incidence of PCA. No patients with sera positive for IFA were detected among the 22 PCA-positive patients. There is no evidence for humoral derangement of the gastric autoimmunity in chronic alcoholics.

0266 GASTRIN LEVELS AFTER PROXIMAL GASTRIC VAGOTOMY. (Eng.) Hayes, J. R.; Ardill, J.; Kennedy, T. L.; Buchanan, K. D. (Royal Victoria Hosp., Belfast, Ireland). *Ir. J. Med. Sci.* 144(9):349-354; 1975.

Fasting gastrin levels were compared in 16 patients before and after selective vagotomy with drainage and in 15 patients before and after proximal gastric vagotomy without drainage. In addition, the gastrin response to ingested protein after proximal gastric vagotomy was studied. In both groups there was a significant rise in fasting gastrin levels (45-85 pg/ml and 70-84 pg/ml, resp.) following the operative procedures, but no significant difference between gastrin levels after selective vagotomy and after proximal gastric vagotomy was found. The gastrin output in response to protein in six patients with proximal gastric vagotomy studied within 2 weeks of operation did not differ from their pre-operative response. The results demonstrate that the retention of an innervated antrum as in proximal gastric vagotomy neither resulted in fasting gastrin levels that were higher than when the antrum was denervated nor in excessive gastrin levels after protein ingestion. In both postoperative groups, insulin hypoglycemia produced a similar rise in gastrin levels: 60-98 pg/ml in patients with selective vagotomy and 55-84 pg/ml in patients with proximal gastric vagotomy. Insulin hypoglycemia is therefore not a specific test of vagal function, and other mechanisms may be involved in the increase in acid secretion seen after insulin.

0267 NUTRITIONAL CONSEQUENCES OF TOTAL GASTRECTOMY. (Eng.) Bradley, E. L., III; Isaacs, J.; Hersh, T.; Davidson, E. D. (Emory Univ. Sch. Medicine, 69 Butler St., Atlanta, GA). *Ann. Surg.* 182(4):415-429; 1975.

The ability to ingest and absorb adequate amounts of nutrients was investigated in 10 patients (7 men and 3 women) who had undergone total gastrectomy without evidence of malignancy. Metabolic balance studies were also performed to discover how effectively these patients could accumulate and use the absorbed nutrients. In the controlled hospital situation, the amount of food ingested was greater than the amount required for maintenance of ideal body weight. Although mild malabsorption of fat and nitrogen was documented, weight gain and positive nitrogen balance occurred. In direct contrast, food intake significantly decreased when the patients returned to their home environment. While severe malabsorption may contribute to malnutrition in the individual patient, the most common mechanism responsible for postoperative malnutrition was inadequate intake. Construction of a Hunt-Lawrence jejunal pouch was not found to favorably affect caloric intake, weight gain, degree of malabsorption, or dumping symptoms. The results indicate that although some degree of malnutrition does result from total gastric resection, in most cases it is mild and potentially correctable.

0268 INTRAGASTRIC MICROBIAL COLONIZATION IN COMMON DISEASE STATES OF THE STOMACH AND DUODENUM. (Eng.) Nichols, R. L.; Smith, J. W. (Veterans Admin. Hosp., Downey, IL 60064). *Ann. Surg.* 182(5):557-561; 1975.

Patients (49) undergoing elective or emergent gastric surgery were examined for the presence of gastric microflora, and the role of this microflora in postoperative wound infection was studied. Gastric needle aspiration was performed at the time of surgery in each case, followed by qualitative aerobic and anaerobic bacteriologic analysis. Isolation of intragastric aerobes and/or anaerobes was possible in 32/49 patients. In 18 patients undergoing elective operation for chronic nonobstructing doudenal ulcer, a gastric microflora was present in only three patients and no postoperative wound infections were observed. In 29 of 31 patients, in other groups of patients with bleeding or obstructing duodenal ulcer, or in those with gastric ulcer or malignancy, intragastric microorganisms were present. Six of the seven postoperative wound infections that developed in these groups of patients were due to one of the same bacteria isolated at the time of original needle aspiration. The authors conclude that the endogenous intragastric microflora is a significant factor in the development of postoperative wound sepsis following gastric resection in those groups of patients with a compromise of their normal gastric antibacterial inhibitory mechanisms.

0298 THE DEFINITION OF RADIOLOGICAL SIGNS IN GASTRIC ULCER AND ASSESSMENT OF THEIR VALIDITY BY INTER-OBSERVER VARIATION STUDY. (Eng.) Schulman, A.; Simpkins, K. C. (General Infirmary, Leeds, England). *Clin. Radiol.* 26(3):311-316; 1975.

The reliability of radiological signs in benign and malignant gastric ulcers was evaluated in an inter-observer variation study using two radiologists and the films from 69 barium meal studies. Only four signs were shown to be valid for predicting the probability of malignancy or benignancy in gastric ulcers. These were the projection or nonprojection of the in-profile ulcer, the presence or absence of mucosal folds, good or poor definition of the in-face ulcer's edge, and extension of radiating folds to the in-face ulcer's edge. An insufficient number of cases prevented the analysis of other signs previously thought to have value in distinguishing benign and malignant lesions: qualities of the in-profile ulcer shape, qualities of the in-face ulcer shape, a single nodule in the floor of the in-profile ulcer, and persistent spasm of the pyloric antrum. Signs of poor validity included various qualities of the surrounding filling defect and of the halo, and nodularity of the ulcer rim. The authors conclude that as defined in the literature, the majority of radiological signs in this field are of uncertain existence. However, the four signs found to be valid in this study do not fully describe the important appearances that may be seen in benign and malignant ulcers and are inadequate to obtain a sufficiently high degree of probability.

0299 THE ACCURACY OF RADIOLOGICAL DIAGNOSIS OF BENIGN, PRIMARILY AND SECONDARILY MALIGNANT GASTRIC ULCERS AND THEIR CORRELATION WITH THREE SIMPLIFIED RADIOLOGICAL TYPES. (Eng.) Schulman, A.; Simpkins, K. C. (Leeds General Infirmary, Leeds, England). *Clin. Radiol.* 26(3):317-325; 1975.

The diagnostic accuracy and reliability of 2 radiologists in regard to the benignancy or malignancy of 145 radiographic representations of gastric ulcers, all with gastrectomy histological proof of benignancy or malignancy, were evaluated. A radiological diagnosis of malignancy was 98.6% reliable. A diagnosis of benignancy was less reliable (85.4% true positives), but this was a surgical series containing over one-third malignant ulcers. A correct diagnosis was made in 99.5% of the proven benign ulcers, but in only 68.6% of the proven malignant ulcers. Analysis of the pathology reports on the malignant ulcers showed that it was mainly those arising on the basis of pre-existing benign ulcers (i.e., secondarily malignant ulcers) that were wrongly diagnosed radiologically, thus suggesting that they have a fundamentally different radiographic appearance from that of primarily malignant ulcers. The ulcers could be divided into three simplified radiological types based on their in-profile appearances: type 1 (projecting), type 2 (intraluminal), and type 3 (so shallow as to be neither projecting nor intraluminal). Statistical association with the histological types led to the conclusions that radiological type 2 or 3 ulcers should be diagnosed as almost certainly malignant and that radiological type 1 ulcers are almost always benign but should be followed up until healed because the rare secondarily malignant ulcers are also usually of this type.

0300 THE EFFECT OF INTRAGASTRIC NEUTRALIZATION ON THE GASTRIC ACID RESPONSE TO ANTRAL DISTENSION IN MAN. (Eng.) Bergegardh, S.; Knutson, U.; Olbe, L. (Dept. Surgery II, Sahlgrenska Sjukhuset, Univ. Goteborg, S-413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 10(6):625-631; 1975.

The gastric acid secretion in response to graded antral distension was determined in 7 healthy subjects and in 24 peptic ulcer patients (6 with gastric ulcers, 7 with quiescent duodenal ulcers, and 11 with active duodenal ulcers) with water perfusion or alkaline buffer perfusion of the stomach. The resultant intragastric pH was 1.8-3.0 for the controls and 6.2-8.3 for the peptic ulcer patients. Intragastric neutralization increased the basal acid secretion in healthy subjects and gastric ulcer patients but did not change the basal acid secretion in duodenal ulcer patients. Distension of the antrum produced the same secretory effect with and without intragastric neutralization. No increased acid response occurred in healthy subjects. A slight acid response occurred in patients with a quiescent duodenal ulcer or a gastric ulcer, and a more pronounced acid response was seen in patients with an active ulcer, amounting to about 30% of the peak acid response to pentagastrin. The results show that: a) peptic ulcer patients, particularly patients with an active duodenal ulcer, are more sensitive to the acid secretory effect of antral distension than healthy subjects; b) increasing the intragastric pH above 2.0 does not enhance the acid response to antral distension; and c) the acid secretory effect of antral distension is markedly less in man than the effect reported for the dog.

0301 GASTRIC SECRETORY RESPONSE TO GRADED DOSES OF PENTAGASTRIN ALONE OR IN COMBINATION WITH CARBACHOLINE IN UNOPERATED DUODENAL ULCER PATIENTS. (Eng.) Roland, M. (Aker Univ. Hosp., Oslo 5, Norway). *Scand. J. Gastroenterol.* 10(6):603-608; 1975.

The sensitizing effect of carbacholine on pentagastrin-stimulated gastric secretion in six unoperated duodenal ulcer patients was investigated. On different days, pentagastrin was given in doses of 0.15, 1.5, and 15 μg/kg/hr, either alone or in combination with carbacholine (2 μg/kg/hr). There were no significant differences between mean acid or pepsin outputs or mean volumes of gastric juice after infusion of pentagastrin alone or pentagastrin plus carbacholine at any dose step of pentagastrin. The dose of pentagastrin required to elicit half maximal acid output (K_m) and the calculated maximal acid output (V_{max}) were the same for pentagastrin alone and pentagastrin plus carbacholine. The authors conclude that carbacholine did not increase the sensitivity of the parietal cells to pentagastrin in the unoperated duodenal ulcer patients.

0302 A STUDY OF THE RELATIONSHIP BETWEEN SERUM GROUP I PEPSINOGEN LEVELS AND GASTRIC ACID SECRETION. (Eng.) Samloff, I. M.; Secrist, D. M.; Passaro, E., Jr. (Harbor General Hosp., 1000 W. Carson St., Torrance, CA 90509). *Gastroenterology* 69(6):1196-1200; 1975.

Serum group I pepsinogen (PG I) levels, basal acid output, and peak acid output (PAO) were determined in 120 patients, 54 with duodenal ulcer, 14 with prepyloric ulcer, 12 with gastric ulcer, and 40 without ulcer. The correlation between serum PG I and PAO was statistically significant (r=0.736, $p<0.001$) up to a serum PG I level of 250 ng/ml. Serum PG I levels above 250 ng/ml were associated with a plateau in the PAO. Each of eight patients with a serum PG I of less than 40 ng/ml had a PAO of less than 10 mEq/hr. Of 34 patients with a serum PG I over 200 ng/ml, 29 (85.3%) had a PAO of greater than 40 mEq/hr and all had a PAO above 34 mEq/hr. Of 51 patients with a serum PG I between 60 and 150 ng/ml, 47 (92.2%) had a PAO of 10-40 mEq/hr. The results indicate that a significant relation exists between the concentration of PG I in serum and the acid secretory capacity of the gastric mucosa.

0303 TREATMENT OF DUODENAL ULCER BY METIAMIDE: A MULTICENTRE TRIAL. (Eng.) Celestin, L. R.; Harvey, V.; Saunders, J. H. B.; Wormsley, K. G.; Forrest, J. A. H.; Logan, R. F. A.; Shearman, D. J. C.; Fermont, D.; Haggie, S. J.; Wyllie, J. H.; Albinus, M.; Thompson, M. H.; Venables, C. W. (Frenchay Hosp., Bristol, England). *Lancet* 2(7939):779-781; 1975.

A multicenter endoscopically monitored double-blind trial was undertaken to assess whether metiamide administration would increase the rate of healing of duodenal ulcers as compared to use of a placebo. Of 68 patients with endoscopically confirmed duodenal ulceration, 36 received 1 g or 1.3 g metiamide and 32 placebo daily for 4 weeks. Healing of duodenal ulcers was significantly increased in patients receiving metiamide (67%) compared with those on placebo (25%). There was also an associated significant decrease in daytime pain and antacid consumption in those on metiamide. It is concluded that a histamine H_2-receptor antagonist can promote healing of duodenal ulceration.

SMALL INTESTINE

0338 PROXIMAL SMALL BOWEL TRANSIT PATTERN IN PATIENTS WITH MALABSORPTION INDUCED BY BOVINE MILK PROTEIN INGESTION. (Eng.) Liu, H.-Y.; Whitehouse, W. M.; Giday, Z. (Univ. Michigan Medical Sch., Ann Arbor, MI). *Radiology* 115(2):415-420; 1975.

The effect of bovine milk ingestion on the radiologic patterns of proximal small bowel transit was examined in seven patients with bovine milk or milk protein-inducible transient intestinal malabsorption. All seven allergic patients exhibited radiologic signs of rapid transit of ingested barium through the proximal small intestine at 1.5 and 8 hr following p.o. challenge with bovine milk or milk protein solution. Control studies in the same patients without prior milk challenge revealed significantly more leisurely progress of contrast medium in the proximal small bowel. The possible pathogenic role of such hasty transit through the functionally most effective portion of the digestive tract in patients with malabsorption emphasizes the physiologic importance of roentgen examination of motility patterns in this segment of small bowel.

SMALL INTESTINE

Malabsorption

0366 FREE INTRINSIC FACTOR IN THE SMALL INTESTINE IN MAN. (Eng.) Kapadia, C. R.; Mathan, V. I.; Baker, S. J. (Veterans Admin. Hosp., Medical SVC,W. Spring St., West Haven, CT 06516). *Gastroenterology* 70(5):704-706; 1976.

Human jejunal and ileal contents and ileostomy effluents were examined for the presence of free intrinsic factor (IF) to determine if IF in the small intestine is physiologically active. IF was measured either by zirconium phosphate gel and the binding IF antibody, or by hemoglobin-coated charcoal and the blocking IF antibody in jejunal aspirates from six healthy control subjects and four with tropical sprue. IF was detected in 9 of 10 jejunal and 3 of 5 ileal aspirates, and in 1 of 3 ileostomy effluents. The IF in the ileal effluent was shown to be physiologically active; administration of effluent containing free IF and radioactive vitamin B_{12} to two subjects who lacked endogenous IF showed that the labeled vitamin was well absorbed. The demonstration of free IF in the lumen of the small intestine establishes the existence of one of the essential conditions that would enable vitamin B_{12} excreted in the bile to be reabsorbed in the ileum, thus maintaining the enterohepatic circulation.

0367 KINETICS OF BILE ACID METABOLISM IN EXPERIMENTAL BLIND LOOP SYNDROME. (Eng.) Bender, S.; Sauer, H.; Hoffmann, D. (Clinics of the J. W. Goethe-Univ., Frankfurt/M, W. Germany). *Gut* 16(12):927-931; 1975.

Bile salt metabolism was studied using Eriksson's washout technique in an experimental model of the contaminated small bowel syndrome of female Wistar rats. Bile salt secretion rate was increased from 204.7 ± SD 36.5 µmol/100 g/24 hr to 329.9 ± 146.6 pool size from 13.4 ± 5.4 µmol/100 g to 42.5 ± 7.2, and biliary flow from 6.6 ± 1.72 ml/100 g/24 hr to 8.4 ± 2.1. The author concludes that detailed analysis of washout curves gives indirect evidence of a short-ciruit jejunohepatic shunt in the model of contaminated small bowel syndrome. Parameters of this shunt were calculated with 9.1 µmol/100 g for short-circuit pool size and 13.8 for its circulation frequency.

0368 PROSPECTIVE COMPARISON OF INDIRECT METHODS FOR DETECTING LACTASE DEFICIENCY. (Eng.) Newcomer, A. D.; McGill, D. B.; Thomas, P. J.; Hofmann, A. F. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *N. Engl. J. Med.* 293(24):1232-1235; 1975.

Four indirect methods of detecting lactase deficiency were tested prospectively in 25 subjects with biopsy-proven lactase deficiency and in 25 subjects with normal lactase activity to compare sensitivity, specificity, and convenience of the tests. Each subject underwent all four tests. On one day, a p.o. lactose load (50 g in 500 ml water) was followed by a blood test (capillary plasma glucose) and two breath tests (hydrogen and $^{14}CO_2$). On another day, a p.o. lactose load was given together with ethanol, and capillary plasma concentration was measured. The sequence of tests was randomized. After ingestion of lactose, containing 1-^{14}C lactose, breath hydrogen was abnormally elevated in all 25 lactase-deficient subjects (> 0.30 ml/min at 2 hr); breath $^{14}CO_2$ was below the normal range in 23; and in 19 the plasma glucose increased by less than 20 mg/dl. When lactose and ethanol were given together, the rise in plasma galactose remained under 5 mg/dl in 24 of the lactase-deficient subjects. The specificity of the four tests was excellent, with only one false-positive plasma glucose test. Measurement of breath hydrogen was sensitive and specific, and did not require ethanol or isotopes. It was noninvasive, and was not influenced by gastric emptying or metabolic factors. The authors suggest that measurement of breath hydrogen is the most suitable test for population screening for lactase deficiency

0369 SECRETION OF EXOCRINE PANCREATIC ENZYMES IN PATIENTS WITH TROPICAL SPRUE, FOLLOWING STIMULATION BY A TEST MEAL. (Eng.) Balagopal, G.; Jacob, R.; Swarnabai, C.; Kapadia, C. R.; Mathan, V. I.; Baker, S. J. (Christian Medical Coll. Hosp., Vellore, Tamil Nadu, India). *Indian J. Med. Res.* 63(8):1138-1149; 1975.

Pancreatic function in response to a test meal was compared in 24 control subjects, 24 patients with tropical sprue, and 7 patients with chronic pancreatitis. The test meal, administered p.o., contained spray dried milk powder (48 g), dextrose (15 g), groundnut oil (6 g), polyethylene glycol (1% solution, 50 ml), and water (to make 250 ml). The nonabsorbable marker was used to estimate recovery of the meal from the duodenum. Trypsin, amylase, and esterase were measured, and the results were expressed both as concentration and total enzyme output per hour. Patients with tropical sprue had a significant reduction in pancreatic function compared with control subjects, as shown by a decreased output and decreased concentration of all three enzymes. The output of pancreatic enzymes in the sprue patients showed a significant correlation with the serum albumin concentration but not with any parameter of intestinal structure or function. The authors conclude that any one enzyme measurement would be sufficient for detection of severe pancreatic dysfunction. However, for studying minor degrees of pancreatic hypofunction, several enzymes should be measured.

LARGE INTESTINE

0387 HUMAN COLONIC ADENOCARCINOMA CELLS. I. ESTABLISHMENT AND DESCRIPTION OF A NEW LINE. (Eng.) Tom, B. H.; Rutzky, L. P.; Jakstys, M. M.; Oyasu, R.; Kaye, C. I.; Kahan, B. D. (Veterans Admin. Lakeside Hosp., Chicago, IL 60611). *In Vitro* 12(3):180-191; 1976.

A series of human colonic epithelial cell lines was cultured from a single adenocarcinoma patient, LS-180, the original adenocarcinoma; LS-174T, a trypsinized variant; and normal colonic tissue. The malignant cells, 20-40 μm in diameter and oval to polygonal, exhibited characteristics of normal colonic mucosal cells, namely, abundant microvilli prominent in secretory cells, and the presence of intracytoplasmic mucin vacuoles. The cultured adenocarcinoma cells demonstrated neoplastic properties by producing high levels of carcinoembryonic antigen (CEA) and by their ability to be propagated in hamster cheek pouches and in immunodeprived mice. The CEA production by the newly established line LS-180 released 900 times more CEA per cell into the culture medium and bore 30 times more cell-associated material than the established line, HT-29. These cell lines may permit detection of distinctive chemical, physiological, pharmacologic, and immunologic characteristics of neoplastic colonic cells.

0388 CARCINOEMBRYONIC ANTIGEN: ISOLATION OF A SUB-FRACTION WITH HIGH SPECIFIC ACTIVITY. (Eng.) Rogers, G. T.; Searle, F.; Bagshawe, K. D. (Charing Cross Hosp., London W6 8RF, England). *Br. J. Cancer* 33(4):357-362; 1976.

Four subfractions of carcinoembryonic antigen (CEA) were obtained by chromatography of conventional CEA on concanavalin A (Con A) Sepharose, and their immunoreactive contents were determined. Comparative studies showed that a fraction eluted with 2% methylglucoside (CEA 2B) had the highest activity, with a potency (60 U/μg) twice that of unfractionated CEA, although appreciable activity was also found in the other fractions. The amino acid composition of CEA 2B was similar to that reported for conventional CEA but there was a lower content of neutral hexoses and a comparatively high content of *N*-acetylglucosamine. Experiments with a pool of sera from 11 patients with colonic cancer, which had been fractionated on Con A-Sepharose, showed that nearly all CEA activity was contained in a fraction eluted with 2% methylglucoside.

0389 MIGRATION INHIBITION WITH VARIOUS CELL FRACTIONS IN HUMAN COLORECTAL CANCER. (Eng.) Armitstead, P. R.; Gowland, G. (Univ. Leeds, The General Infirmary, Leeds, U.K.). *Gut* 16(12): 968-972; 1975.

The unseparated WBC, separated mononuclear cells, and granulocytes of six control subjects and nine patients with colorectal cancer were studied by direct cell migration inhibition. A migratory index was calculated from migration in the presence and absence of a perchloric acid extract of large bowel tumors. In 10% homologous AB serum, no significant migration inhibition occurred with any of the cells from control subjects. Five of the nine cancer patients showed significant inhibition with their unseparated WBC, seven of seven with their mononuclear cells, and none of nine with their granulocytes. In 10% autologous serum, some controls exhibited migration inhibition with their unseparated WBC and their granulocyte fraction, but not with the mononuclear cell fraction. In the presence of autologous serum, migration inhibition was also apparent in the granulocyte fraction of the cancer patients. It is concluded that (a) with a soluble tumor antigen preparation, a mononuclear cell population increases the sensitivity of the direct migration inhibition test and (b) autologous serum may interfere directly with the migration of granulocytes by an action not dependent upon the release of inhibitory factors from sensitized lymphocytes. This could explain some of the inconsistencies of the assay when using an unseparated WBC population.

0390 PREMALIGNANCY OF THE MUCOSAL POLYP IN THE LARGE INTESTINE: I. HISTOLOGIC GRADATION OF THE POLYP ON THE BASIS OF EPITHELIAL PSEUDOSTRATIFICATION AND GLANDULAR BRANCHING.

(Eng.) Kozuka, S. (Nagoya Univ. Sch. Medicine, 65 Tsurumaicho, Showaku, Nagoya, 466, Japan). *Dis. Colon Rectum* 18(6):483-493; 1975.

Two types of classification for the objective gradation of premalignant stages of mucosal polyps in the large intestine are presented. Biopsy specimens of mucosal polyps and invasive carcinomas of the large intestine and rectum (130) were collected from 360 Japanese patients. The first classification system is based mainly on pseudostratification of the glandular epithelium, and the second on branching of the gland. Six stages of the former are described. Grade 0 differs from normal mucosa only in mucosal thickening. Grade I has enlargement of glandular lumens and elongation of glands. Grade II is characterized by crowding of tall, narrow epithelial cells and elongation of epithelial nuclei, but no psuedostratification. Grade III shows apparent pseudostratification and frequent mitotic figures, but the level of nuclear position is limited to the basal half of the height of the glandular epithelium (except for mitotic nuclei). Grade IV is characterized by severe pseudostratification of glandular epithelium, but only mitotic nuclei occupy the upper epithelium. Grade V has extremely severe pseudostratification of the glandular epithelium and nuclei scattered throughout the height of the epithelium. This grading system when applied to the biopsy specimens, was in excellent agreement with increases in mitotic figures, nuclear chromatin, and pleomorphism, and decreases in mucin secretion. Foci and/or tendency towards glandular fusion and/or glands back-to-back were found in 26/28 polyps with grade V pseudostratification, compared to 2/202 polyps of grade 0-IV. Adenomatous residues of grade III and/or IV were found in 42/130 cases of invasive carcinoma, suggesting an intimate relation of adenoma to the induction of adenocarcinoma. Hyperplastic residues of grade I or II pseudostratification were found in about half of 130 cases. The extent of glandular branching paralleled the pseudostratification grading; most polyps with secondary branching had a narrower stroma than those that had primary branching only. Foci and/or tendency towards glandular fusion and/or glands back-to-back were found in 25/56 with secondary branching, in 3/121 with primary branching only, and in 1/53 without branching. The results suggest a gradual progression from normal tissue to invasive carcinoma through the process of hyperplasia, adenoma, and carcinoma *in situ*.

0391 PREMALIGNANCY OF THE MUCOSAL POLYP IN THE LARGE INTESTINE: II. ESTIMATION OF THE PERIODS REQUIRED FOR MALIGNANT TRANSFORMATION OF MUCOSAL POLYPS.

(Eng.) Kozuka, S.; Nogaki, M.; Ozeki, T.; Masumori, S. (Nagoya Univ. Sch. Medicine, 65 Tsurumaicho, Showaku Nagoya, 466, Japan). *Dis. Colon Rectum* 18(6):494-500; 1975.

The relation between age of the patient and histologic grade, based on epithelial pseudostratification, of mucosal polyps (331 polyps from 324 patients) was compared with the relation between age and histologic grade of invasive carcinoma of the large intestine (261 surgical cases and 3,178 autopsy cases). Age ranged widely from newborn to over 95 yr, but the average age of patients increased steadily with the advance of histologic atypism from 40.7 yr with grade I polyp to 58.7 yr with invasive cancer. From the differences in average ages of the patients, intervals that might be required for polyps of each grade to become malignant were calculated. The results were 3.6 yr for polyps of grade V, 8.3 yr for grade IV, 11.4 yr for grade III, 13.1 yr for grade II, and 18 yr for grade I. Grade 0 did not follow this general progression; the age difference from patients whose cancers were found at autopsy was 15.1 yr. However, this group was considerably smaller than the others studied. The authors suggest that examination and polypectomy at 5-yr intervals after 35 yr of age might be sufficient to protect against invasive carcinoma of the large intestine.

0392 RISK OF RECURRENCE OF COLON POLYPS.

(Eng.) Henry, L. G.; Condon, R. E.; Schulte, W. J.; Aprahamian, C.; DeCosse, J. J. (Wood Veterans Admin. Center, Milwaukee, WI). *Ann. Surg.* 182(4):511-515; 1975.

Patients (268) who had a polypectomy were followed up to 20 yr with semiannual proctosigmoidoscopic and barium enema examinations. Patients having coexisting carcinoma, chronic inflammatory disease, and those lost to follow-up were excluded; 154 patients followed for a mean of 7 yr comprised the study group. Thirty percent developed recurrent polyps. The risk of recurrence during the first year was 16 times that expected in a population of similar age and sex, but thereafter diminished steadily. After 48 months, risk of polyp recurrence was little higher than the incidence expected in a normal population. Neither age, presenting symptoms, nor the site or size of the initial polyp(s) were of any prognostic value regarding recurrence. Patients presenting with a villous adenoma or with more than three polyps had a significantly increased risk of recurrence. Of those who developed one recurrent polyp, one-third developed another recurrence. In this subgroup, although numbers were small, the risk of developing further recurrence could persist indefinitely. The overall incidence of colonic carcinoma may have been increased, but the location of subsequent cancer was not related to the site of a previously excised polyp.

0393 A REAPPRAISAL OF STAGING AND THERAPY FOR PATIENTS WITH CANCER OF THE RECTUM: II. PATTERNS OF PRESENTATION AND OUTCOME OF TREATMENT.

(Eng.) Feinstein, A. R.; Schimpff, C. R.; Hull, E. W. (West Haven Veterans Admin. Hosp., West Haven, CT). *Arch. Intern. Med.* 135(11):1454-1462; 1975.

Two new systems of staging were employed for analysis of the anatomic and symptomatic features at presentation (zero time), the selection bias in choice of treatment, and the outcome of 318 patients with rectal cancer. One system, based on data available before the zero time treatment, was applied to all patients regardless of therapy. The other system included information noted after surgical exploration and was applied to patients whose rectal cancer was resected. Selectional bias was evident in therapeutic decisions. The patients chosen for surgical exploration and possible resection came mainly from prognostically favorable stages and had higher survival rates than the inoperable patients even when the tumor was not resected. In patients with tumors located 8 cm or higher above the anus, survival rates in each composite symptom-anatomic stage were essentially similar with radical and simple resections. Radical surgery gave better survival rates than simple surgery for tumors at 5-7 cm and was an anatomic necessity to remove tumors at 0-4 cm. Regardless of the extensiveness of surgery, the symptom-anatomic stages were directly related to rates of postoperative infection, postoperative death, subsequent quality of life, and deaths due either to cancer or to noncancer causes. This study reaffirms the necessity for incorporating an additional, separate staging of patients' symptoms. The results demonstrate the importance of considering, classifying, and analyzing the total biologic behavior of the tumor, rather than its morphology alone, for estimating prognosis and evaluating treatment in patients with rectal cancer.

0394 FUNCTION OF THE ANAL SPHINCTERS IN PATIENTS WITH INTUSSUSCEPTION OF THE RECTUM. (Eng.) Frenckner, B.; Ihre, T. (Serafimer Hosp., Stockholm, Sweden). *Gut* 17(2):147-151; 1976.

Anal sphincter function was examined in 15 women with intussusception of the rectum (6 with anal incontinence and 9 continent). Anal pressure was recorded continuously during rest, during maximal voluntary squeezing of the anal muscles, and during gradual expansion of the rectum by means of a balloon inserted into the rectal ampulla. The maximal anal pressure at rest was lower ($p<0.001$) in incontinent patients (31 mm Hg ± 5.6) than the continent (67 mm Hg ± 4.3), and the former had significantly smaller relaxations of the internal sphincter upon rectal distension ($p<0.05$). The increase in anal pressure during voluntary squeezing, a function of the external sphincter, did not differ significantly compared with healthy subjects in either incontinent or continent patients. It is concluded that the function of the internal sphincter is impaired in the incontinent patients.

0395 COLONIC MYOELECTRIC ACTIVITY IN THE IRRITABLE BOWEL SYNDROME. (Eng.) Snape, W. J., Jr.; Carlson, G. M.; Cohen, S. (Dept. Medicine, Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 70(3):326-330; 1976.

Rectal and rectosigmoid myoelectric activities were compared in 10 normal subjects and in 12 patients (7 women and 5 men, aged 23-69 yr) with irritable bowel syndrome (IBS) to determine whether the syndrome is principally a motor disturbance of the large intestine. Placement and removal of the electrodes had no adverse effects on the subjects or patients. Basic electrical rhythm (BER), spike potential activity, and intraluminal pressure were recorded in both groups. In each individual, two types of BER were recorded. The major component of the BER had a frequency of about 6 cycles/min while the minor component had a frequency of 3 cycles/min. In normal subjects, the BER was present at 6.0 cycles/min and no spike potential activity was noted. In patients, the BER frequency was 3 cycles/min and spontaneous spike potential and contractile activity were present. The myoelectric activity differed in normal subjects and patients in the percentage of time occupied by each of the two types of BER. In the patients, the slower frequency BER was recorded for a greater proportion (44% of the total BER as compared to 10% for controls) of time in both the rectum and rectosigmoid. In the patients, differences in myoelectric activity could not be correlated with specific symptoms or duration of illness. Neither age nor sex influenced myoelectric parameters. This study failed to demonstrate a difference in basal colonic contractile activity in normal subjects and in patients with the IBS. Under conditions where the motor activity is similar to that in normal subjects, patients with IBS have a significant difference in the properties of the distal large intestine, suggesting that the abnormalities in colonic motor response may be related to the difference in colonic BER.

LARGE INTESTINE

Ulcerative Colitis

0437 THE DIAGNOSIS OF COLITIS BY COLONOSCOPY WITH BIOPSY AND X-RAY EXAMINATION. A BLIND COMPARATIVE STUDY. (Eng.) Myren, J.; Eie, H.; Serck-Hanssen, A. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 11(2):141-144; 1976.

The use of colonoscopy and biopsy in the diagnosis of colitis was compared with x-ray examination in a blind study of 40 patients (21 women). Biopsy specimens (185) were obtained from the rectal and colonic mucosa. The x-ray examination was performed within 1 week after the colonoscopy, using a conventional barium enema. A complete agreement between the colonoscopic diagnosis and that of the directed biopsy was found in 33 cases and major disagreements were found in three cases. A complete agreement between the colonoscopic and x-ray diagnoses were obtained in 22 patients and minor disagreements were seen in 16 cases, most of whom showed unspecific nonulcerative colitis. In three cases with ulcerative colitis, a normal colon was found by x-ray. A higher percentage of cases showed decreased haustration by x-ray examination than by colonoscopy, whereas a fairly equal percentage of ulceration was detected by the two methods. Erosions, mucus covering, edema, vascular injection, and bleeding were not detected by x-ray examination. The results demonstrate that differentiation between a normal colonic mucosa and that with alterations without ulcerations (unspecified colitis) is difficult with x-ray examination. However, colonoscopy results agreed favorably with those of histology on directed biopsy. A good correlation was found between colonoscopy and x-ray examination in the detection of mucosal ulcerations.

0438 DIARRHOEA AND COLITIS ASSOCIATED WITH ANTIBIOTIC TREATMENT: A REPORT OF 16 CASES. Gibson, G. E.; Rowland, R.; Hecker, R. (Royal Adelaide Hosp., Adelaide, Australia). *Aust. N.Z. J. Med.* 5(4):340-347; 1975.

A series of 16 patients (19 to 85-yr-old, 5 men and 11 women) with diarrhea of varying severity developing within 21 days of antibiotic therapy is reported. In 12/16 cases, the onset of symptoms followed the administration of lincomycin or clindamycin; ampicillin was implicated in 2 and methicillin and bactrim in one each. All patients who had taken lincomycin developed diarrhea within 14 days. Three cases are briefly cited as examples of mild, moderate, and severe disease. A 29-yr-old woman developed diarrhea 4 days after starting clindamycin, with up to 10 stools/day, blood and mucus in the stools, and a 14-lb weight loss. Sigmoidoscopy revealed low grade colitis with a histologic diagnosis of nonspecific colitis. A 74-yr-old woman on lincomycin and cephalexin developed diarrhea 8 days after a total hip replacement. Thirty days later she was febrile, confused, dehydrated, and continually incontinent. Barium enema showed widespread ulceration of the colon, and sigmoidoscopy revealed pseudomembranous colitis. Severe colitis developed over 40 days in an 83-yr-old woman on prophylactic lincomycin after total hip replacement. Eighteen days postoperatively, a barium enema revealed sigmoid diverticular disease. Sigmoidoscopy at 30 days showed acute colitis. Toxic megacolon developed by the 40th postoperative day. Ten of the 16 patients made a complete recovery, 2 achieved a gradual recovery, and 4 (2 of whom had colectomies) died. This study indicates that colitis developing during or after antibiotic therapy may be pseudomembranous or nonspecific type. The authors conclude that although antibiotics may be implicated in the development of colitis, other etiologic factors should also be considered.

0439 COMPARISON OF BOWEL FUNCTION AFTER ILEORECTAL ANASTOMOSIS FOR ULCERATIVE COLITIS AND COLONIC POLYPOSIS. (Eng.) Newton, C. R.; Baker, W. N. W. (Middlesex Hosp., London WlN 8AA, England). *Gut* 16(10):785-791; 1975.

Bowel habit was studied in 92 outpatients (43 men and 49 women, aged 19-67 yr) with ileorectal anastomosis for ulcerative colitis and compared with that in 45 outpatients (30 men and 15 women, aged 20-72 yr) with ileorectal anastomosis for colonic polyposis. Bowel frequency ranged from 1.7 to 8.7 stools/24 hr (mean, 4.5) in the colitic group compared with a range of 1.3 to 8.1 stools/24 hr (mean, 3.5) in the polyposis group. Eighty-two percent of the colitic group and 95% of the polyposis group had six or fewer bowel actions/24 hr. In those patients with more than six bowel actions/24 hr, a higher percentage (71%) were in poor general condition preoperatively than in the groups with three to six bowel action/24 hr (37%) and less than three/24 hr (24%). Urgency of defecation was rare; 78% of the colitic group and 83% of the polyposis group were able to delay defecation for 30 min or longer. Bowel actions every night and occasional fecal incontinence occurred in small but similar percentages of patients in both groups. Fifty-one percent of patients in the colitic group, as compared with 9% in the polyposis group, were taking regular treatment to improve bowel function. Dietary difficulty was rare after ileorectal anastomosis in both colitic and polyposis groups. The authors conclude that this study provides a valid assessment of bowel function 6 months or more after ileorectal anastomosis for ulcerative colitis.

PANCREAS

0451 ANGIOGRAPHY VS. PANCREATOGRAPHY IN DIAGNOSIS OF CARCINOMA OF THE PANCREAS. (Eng.) Clouse, M.; Gregg, J. A.; Sedgwick, C. E. (New England Deaconess Hosp., Boston, MA). *Radiology* 114(3):605-610; 1975.

The relative efficacy of angiography and pancreatography in the diagnosis of pancreatic carcinoma was compared in 13 patients. Pancreatography provided a correct preoperative diagnosis in all 10 patients studied. In three patients the duct could not be cannulated. Twelve patients underwent angiography, and a correct diagnosis was made in 10. Preoperative diagnosis was not made by either technique in one patient. Pancreatography did not detect carcinoma of the pancreas at an earlier stage than did angiography and resectability of the tumor. Angiography defined the size, extension, and resectability of the tumor, while pancreatography outlined the internal architecture of the gland and duct system. The authors conclude that these procedures should be considered complementary to each other.

0452 ANGIOGRAPHIC FEATURES OF SQUAMOUS CELL CARCINOMA OF THE PANCREAS. (Eng.) Sprayregen, S.; Schoenbaum, S. W.; Messinger, N. H. (Montefiore Hosp., 111 East 210th St., Bronx, NY 10467). *J. Can. Assoc. Radiol.* 26(2):122-124; 1975.

The angiographic findings in squamous cell carcinoma of the pancreas in a 53-yr-old women and a 72-yr-old man are reported. Tumor blushes were present in both cases, and one case showed hypervascularity. These angiographic features distinguish this lesion from the typical adenocarcinoma of the pancreas. It is suggested that squamous cell carcinoma be considered when hypervascularity or a tumor blush is demonstrated in the pancreas.

0453 MANAGEMENT OF PANCREATIC ASCITES. (Eng.) Stephens, D. B.; Martin, C. E.; Sawyers, J. L. (Vanderbilt Univ. Medical Center, Nashville, TN 37210). *South. Med. J.* 68(10):1234-1238; 1975.

Case studies of two patients with persistent pancreatic ascites who were managed successfully by internal drainage are presented. Case 1, a 33-yr-old male alcoholic, presented with epigastric abdominal pain, weakness, and abdominal swelling. Results of a complete blood count and bilirubin determination were normal; the serum albumin concentration was low, while serum alkaline phosphatase, SGOT, and serum amylase were high. An exploratory laparotomy revealed a large retrogastric

LIBRARY U. OF I.

pancreatic pseudocyst involving the head and body of the pancreas. The abdominal cavity contained 3.5 l of ascitic fluid. A cystogastrostomy and liver biopsy were done. Case 2, a 50-yr-old male alcoholic, complained of abdominal pain with persistent nausea and vomiting. Blood count was normal, and bilirubin, alkaline phosphatase, and serum amylase values were high. A barium meal revealed a retrogastric mass, and an exploratory laparotomy showed that the abdominal cavity contained 4 l of ascitic fluid and a large retrogastric pseudocyst. There was a fistula on the anterior surface of the pancreas. An operative pancreatogram revealed a communication with the duct of Wirsung and a small pseudocyst in the tail of the pancreas. A Roux-en-Y limb of jejunum was anastomosed directly to this fistula. Follow-up examinations of both patients failed to demonstrate any recurrence of ascites. A trial of nonoperative treatment with nasogastric intubation and i.v. hyperalimentation is recommended for patients with pancreatic ascites. Patients who fail to improve usually have pancreatic duct disruption and should have internal drainage operation and/or distal pancreatic resection.

PANCREAS

Pancreatitis

0465 THE PATHOGENESIS OF PULMONARY EDEMA IN ACUTE PANCREATITIS. (Eng.) Warshaw, A. L.; Lesser, P. B.; Rie, M.; Cullen, D. J. (Massachusetts General Hosp., Boston, MA 02114). *Ann. Surg.* 182(4):505-510; 1975.

A distinct form of pulmonary injury in pancreatitis characterized by acute pulmonary edema is documented. Acute pulmonary edema associated with acute pancreatitis was seen in 8% of a series of 60 unselected acute pancreatitis patients and clinical findings in 7 cases are reported. The primary identifiable etiologic factors for the pancreatitis were alcohol abuse (3 patients), type IV hyperlipoproteinemia (2), gastrectomy (1), and idiopathic (1). The diagnosis of pancreatitis was made on clinical grounds and on the basis of an elevated serum amylase, and pulmonary edema was diagnosed radiographically in patients in respiratory distress. None of the patients were in respiratory distress on admission or was there any evidence of prior pulmonary disease. In contrast, hyperlipidemia was seen in only 11% of all cases of acute pancreatitis seen during the same period. Serum calcium was below normal in 7/8 cases, and was less than 7.0 mg% in 4/8. Respiratory distress appeared

48-96 hr after admission. Central venous pressure, pulmonary artery pressure, pulmonary capillary wedge pressure, and pulmonary vascular resistance were normal during the periods of respiratory distress. Cardiac index was elevated. In all cases, respiratory treatment, consisting of endotrachial intubation and controlled ventilation with positive end-expiratory pressure, was successful in reversing injury and allowing recovery of normal respiratory function within 1-2 weeks. It is concluded that this peculiar form of pulmonary injury results from a loss of integrity of the alveolar-capillary membrane leading to pulmonary edema. The authors suggest that circulating free fatty acids, phospholipase A, or vasoactive substances may be involved. Apparently the lesion heals during intensive respiratory support.

LIVER AND BILIARY TRACT

0478 COMPARISON OF ALPHA$_1$ FETOPROTEIN RADIOIMMUNOASSAY METHOD AND LIVER SCANNING FOR DETECTING PRIMARY HEPATIC CELL CARCINOMA. (Eng.) Tonami, N.; Aburano, T.; Hisada, K. (Sch. Medicine, Kanazawa Univ., 13-1, Takara-Machi, Kanazawa-Shi, Japan). *Cancer* 36(2):466-470; 1975.

An α_1-fetoprotein (AFP) radioimmunoassay method was routinely used in addition to liver scintigraphy to detect a primary hepatic cell carcinoma, and the diagnostic accuracy of both methods was compared. Twenty-one of 27 cases (78%) with primary hepatic cell carcinoma showed a positive AFP titer of over 200 ng/ml. In three of these AFP-positive cases, no focal defects could be found in liver scintigraphy, although subsequently performed celiac angiography revealed hypervascular shadows. On the contrary, 22 of 27 cases (81%) represented well-defined focal defects on scintigraphy. In four of these cases with a positive scan, the result of AFP was negative. The overall diagnostic accuracy for detecting primary hepatic cell carcinoma with a combination of both methods was 93%.

0479 RADIOIMMUNOASSAY FOR SERUM THYROXINE-BINDING GLOBULIN: RESULTS IN NORMAL SUBJECTS AND IN PATIENTS WITH HEPATOCELLULAR CARCINOMA.

(Eng.) Gershengorn, M. C.; Larsen, P. R.; Robbins, J. (Natl. Inst. Arthritis, Metabolism, Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *J. Clin. Endocrinol. Metab.* 42(5):907-911; 1976.

Thyroxine-binding globulin (TBG) was measured by radioimmunoassay in the sera of 98 healthy donors and 19 patients with hepatocellular carcinoma. The human TBG was purified by affinity, anion-exchange, and gel filtration chromatography. The mean serum TBG concentration in the 98 euthyroid healthy donors was 1.45 ± 0.46 mg/100 ml, which is one-half that previously reported using a similar method. The mean level in females (1.66 ± 0.56) was significantly higher than that in males (1.37 ± 0.37). Comparison of the serum TBG level and the maximum binding capacity of serum TBG for thyroxine (T_4) yielded a molar ratio of 1:1 for T_4 and TBG. The mean serum TBG in the 19 patients with malignancy was 2.10 ± 1.29 mg/100 ml; however, only 2 of these patients had serum TBG levels outside the normal range. The authors conclude that elevated serum TBG is not a "tumor marker" for hepatocellular carcinoma, as was suggested in a previous study.

0480 QUANTITATIVE ASSESSMENT OF HEPATIC FUNCTION BY BREATH ANALYSIS AFTER ORAL ADMINISTRATION OF [^{14}C]AMINOPYRINE.

(Eng.) Hepner, G. W.; Vesell, E. S. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA). *Ann. Intern. Med.* 83(5):632-638; 1975.

The hepatic metabolism rate of dimethylaminoantipyrine (aminopyrine) was assessed in 148 patients (37 with Laennec's cirrhosis, 10 with fatty liver without portal cirrhosis, 19 with hepatitis, 58 with liver cancer, and 24 with benign cholestasis) by measuring the specific activity of $^{14}CO_2$ excreted in breath samples obtained 2 hr after p.o. administration of a trace dose of [^{14}C]aminopyrine. The percentage of administered ^{14}C excreted in $^{14}CO_2$ in 2 hr was 7.0% ± 1.3% in control patients, and significantly less ($p < 0.01$) in patients with portal cirrhosis (2.6% ± 1.2%), fatty liver (4.7% ± 1.1%), hepatitis (2.6% ± 1.4%), and hepatic malignancy (3.5% ± 1.8%). In 16 of 24 subjects with cholestasis not caused by malignant disease, the mean $^{14}CO_2$ excretion was normal. The $^{14}CO_2$ excretion in patients with portal cirrhosis correlated highly with aminopyrine metabolic clearance rate ($r=0.92$), serum albumin ($r=0.75$), and retention of BSP ($r=0.73$). Abnormal $^{14}CO_2$ excretion returned to normal in patients with hepatitis, when the hepatitis resolved. The data suggest that the aminopyrine breath test is a safe, simple, qualitative, and quantitative liver function test.

0481 QUANTITATIVE LIVER IMAGING USING ^{131}ROSE BENGAL AS AN INDEX OF LIVER FUNCTION AND PROGNOSIS.

(Eng.) Gamlen, T. R.; Triger, D. R.; Ackery, D. M.; Fleming, J. S.; Grant, R. W.; Kenny, R. W.; Maciver, A. G.; Wright, R. (Southampton Univ. Hosp., Southampton, England). *Gut* 16(9):738-743; 1975.

Over a 2-yr period, 94 studies were performed on 84 patients with a variety of hepatic disorders employing a technique for quantitatively assessing hepatic function by direct measurement of liver parenchymal cell uptake of ^{131}I rose bengal (using a scintillation camera with a digital store and retrieval system). The diagnosis in each case was established by liver biopsy or laparotomy. The results were compared with the clinical, biochemical, and histological assessment of the patients. A good correlation was found between the half-time for hepatic uptake of ^{131}I rose bengal and the histological changes, as well as with clinical prognosis measured in terms of clinical improvement or deterioration to death. The rate of liver uptake was found to be a better index than the clearance of radioisotope from the blood and was superior to conventional biochemical investigations in both icteric and anicteric patients. The test was not shown to be of clinical value in discriminating between intra- and extrahepatic causes of jaundice. The authors suggest that this technique may provide a safe and sensitive method for assessing the severity of liver dysfunction and also for monitoring clinical progress, especially in situations where liver biopsy may be unreliable or hazardous.

0482 THE VALUE OF THE RADIO-ISOTOPE HEPATOGRAM IN THE JAUNDICED PATIENT.

(Eng.) Watson, A.; Bone, D. E.; Testa, H. J.; Torrance, B. (Royal Lancaster Infirmary, Lancaster, England). *Br. J. Surg.* 62(10):781-787; 1975.

^{131}I rose bengal given i.v. was employed in a noninvasive technique using a computer-linked gamma system equipped with an electronic light pen for the study of liver function in 80 jaundiced patients. Count rates were determined during hepatic uptake, and biliary excretion was recorded over the liver, biliary tract, and duodenum. Blood clearance of the isotope was simultaneously measured and from these data, the $T_{1/2}$ of uptake, the plasma retention, and the excretion quotient were determined. The results showed that by qualitative assessment of the uptake and excretory phases of the hepatogram and by determination of the excretion quotient, jaundice was classified with an 86% accuracy in cases where the diagnosis was not apparent from clinical and biochemical data. The $T_{1/2}$ of uptake correlated well with BSP retention in a nonjaundiced patient, and when applied to patients with obstructive jaundice enabled the progress of hepatocellular impairment with time and its recovery after relief of the obstruction to be studied.

0483 ^{67}GALLIUM ACCUMULATION IN HEPATIC ACTINOMYCOSIS. (Eng.) Chandarlapaty, S. K. C.; Dusol, M., Jr.; Edwards, R.; Pereiras, R., Jr.; Clark, R.; Schiff, E. R. (Veterans Admin. Hosp., 1201 N.W. 16th St., Miami, FL 33125). *Gastroenterology* 69(3):752-755; 1975.

A case of actinomycosis involving the liver that could be elucidated by ^{67}gallium citrate is reported in a 47-yr-old man. The liver scan with ^{99m}TcS colloid showed multiple areas of focal abnormalities. ^{67}Gallium citrate liver scan showed these areas to concentrate intensely. Actinomycosis may mimic the clinical picture of a malignant neoplastic process, making the differential diagnosis of ^{67}Ga-positive lesions of the liver more difficult.

0484 ELECTROPHORETIC IDENTIFICATION OF AN ISOENZYME OF AMYLASE WHICH INCREASES IN SERUM IN LIVER DISEASES. (Eng.) Warshaw, A. L.; Bellini, C. A.; Lee, K.-H. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 70(4):572-576; 1976.

Isoenzymes of amylase in the sera of 72 persons (37 normal controls and 35 patients with elevated serum amylase concentrations) were studied using polyacrylamide gel electrophoresis and a direct saccharogenic assay for amylase activity. Two major peaks of amylase activity with mobilities similar to pancreatic and salivary amylases were apparent in the control sera. In 11 patients with acute pancreatitis, the area of activity corresponding with pancreatic amylases increased disproportionately. Electrophoretic patterns of amylase activity in the urine of normal subjects and patients with pancreatitis were almost identical to the respective serum patterns from the same persons. In contrast, a prominent slower-moving peak of amylase activity occurred in the serum of 8/12 patients who had hyperamylasemia associated with various liver diseases. Traces of this third peak were identifiable in one-third of normal serum specimens, but no increases in its activity were observed in any specimen from 11 patients with pancreatitis or from 12 other patients with hyperamylasemia unassociated with liver disease. The slower-moving peak was absent from the urine of patients whose serum contained it. The origin of the slower-moving serum amylase appearing in patients with liver disease was not established by these studies. The authors suggest that either the hepatic amylase liberated from damaged liver cells or the metabolism of an amylase not originating in the liver is altered as a result of liver dysfunction.

0485 ABNORMAL ERYTHROCYTE METABOLISM IN HEPATIC DISEASE. (Eng.) Smith, J. R.; Kay, N. E.; Gottlieb, A. J.; Oski, F. A. (Veterans Admin. Hosp., Irving Ave. and Univ. Place, Syracuse, NY 13210). *Blood* 46(6):955-964; 1975.

RBC metabolism was studied in 114 patients with severe hepatic disease. Heinz body formation after incubation of RBC's with acetylphenylhydrazine was significantly higher in patients than in healthy or hospitalized controls. RBC-reduced glutathione levels were lower than those of controls before and after incubation with acetylphenylhydrazine, and patients with the highest Heinz body counts had the lowest reduced glutathione levels. RBC methylene blue-stimulated hexose monophosphate (HMP) shunt metabolism and glucose recycling through the shunt were significantly lower in patients with active hepatic disease than in controls. There was no difference in resting HMP shunt activity or in resting recycling of glucose. Despite impairment of shunt metabolism, total glucose consumption was greater in the patients. Those with the lowest stimulated HMP shunt metabolism and glucose recycling had the highest Heinz body counts, lowest reduced glutathione, and highest total glucose consumption. A continuum of abnormal shunt metabolism was seen, from a mild reduction of stimulated HMP shunt activity to a severe combined decrease in both the HMP shunt and glucose recycling. Glutathione reductase, glutathione peroxidase, glucose-6-phosphate dehydrogenase, and transketolase were normal or increased. Sequential studies were done on 11 patients who had abnormal metabolic studies. Coincident with improvement of HMP shunt metabolism, the Heinz body counts became lower, reduced glutathione higher, hematocrit higher, and liver function improved. Impaired HMP shunt metabolism appears to be a common acquired RBC abnormality in patients with severe, active liver disease.

0486 LIPOPROTEIN PATTERN IN ACUTE AND CHRONIC LIVER DISEASE. (Ger.) Vogt, N.; Englhardt, A. (Medizinische Klinik der Universitat Marburg/Lahn, Marburg, Germany). *Dtsch. Med. Wochenschr.* 100(42):2156-2160, 1975.

Serum lipids were measured by lipoprotein electrophoresis in 115 patients with various forms of liver disease. There was a reduction in α-lipoproteins and an increase in β-lipoproteins, as well as a reduced separability of pre-β and β fractions in patients with acute viral hepatitis. All these changes regressed completely with healing. Similar changes were also shown in chronic liver disease and were most marked in acute liver failure. The changes were also marked in decompensated liver cirrhosis and chronic progressive hepatitis, and less marked in chronic persistent hepatitis and compensated liver cirrhosis. In patients with fatty livers there were no characteristic findings other than a slight increase in pre-β lipoproteins. The lipoprotein pattern was markedly changed in cases with tumor in the region of the gallbladder, but similar changes were also noted with tumors at other sites. Changes in electrophoretic lipoprotein pattern are, therefore, unlikely to be liver-specific.

0487 ALPHA-1-ANTITRYPSIN DEFICIENCY AND LIVER DISEASE IN ADULTS. (Eng.) Triger, D. R.; Millward-Sadler, G. H.; Czaykowski, A. A.; Trowell,

LIBRARY U. OF I.

J.; Wright, R. (Radcliffe Infirmary, Oxford, England). *Q. J. Med.* 45(178):351-372; 1976.

Clinical, biochemical, histological, and genetic studies were performed on 13 patients (aged 16-73 yr) from 12 families with liver disease and abnormal alpha-1-antitrypsin. Long-term observation of several patients suggested that the liver disease may be only slowly progressive. Death from hepatic failure was the most common outcome, but one patient developed a malignant hepatoma and two others died because of intraperitoneal hemorrhage due to ruptured cirrhotic nodules. The most useful screening test in liver disease was found to be the demonstration of PAS-positive globules in liver biopsy material, which is diagnostic when shown to be antigenically identical with alpha-1-antitrypsin by immunofluorescence or immunoperoxidase. Serum estimation of alpha-1-antitrypsin deficiency was performed by immunoelectrophoretic and immunodiffusion techniques. Both methods of estimation, however, were of limited value since wide variations in the serum values are commonly found in normal and abnormal states. Genotyping was carried out using starch gel electrophoresis and although of value in family studies, its value as a diagnostic aid was limited because of technical difficulties and also because alpha-1-antitrypsin accumulation in the liver may be found in both homozygous and heterozygous states. The authors suggest that adult liver disease associated with abnormalities in alpha-1-antitrypsin may be more common than has been reported. This condition should be systematically sought in all cases of liver disease of uncertain etiology.

0488 LIVER, LUNG AND MALIGNANT DISEASE IN HETEROZYGOUS (Pi MZ) α_1-ANTITRYPSIN DEFICIENCY. Eriksson, S.; Moestrup, T.; Hagerstrand, I. (Malmo General Hosp., Malmo, Sweden). *Acta Med. Scand.* 198(4):243-247; 1975.

The occurrence of PAS-positive, diastase-resistant, inclusion bodies in hepatocytes was used as a marker of heterozygous (Pi MZ) α_1-antitrypsin deficiency to study the frequency of lung, liver, and malignant disease in a consecutive autopsy material from 700 cases. Typical PAS-positive inclusion bodies were found in the liver in 26 (3.7%) cases. In these 26 subjects both liver (cirrhosis or fibrosis) and lung disease (emphysema) were significantly more prevalent ($p<0.001$) than among PAS-negative controls. The prevalence of malignant disease did not differ between the groups. The results are consistent with the concept that heterozygous (Pi MZ) α_1-antitrypsin deficiency predisposes to both liver and lung disease but does not influence the survival rate.

0489 THE ULTRASTRUCTURE OF HEPATOCYTES IN ALPHA-1-ANTITRYPSIN DEFICIENCY WITH THE GENOTYPE Pi$_{--}$. (Eng.) Feldmann, G.; Martin, J.-P.; Sesboue, R.; Ropartz, C.; Perelman, R.; Nathanson, M.; Seringe, P.; Benhamou, J.-P. (INSERM, Hopital Beaujon, 92110 Clichy, France). *Gut* 16(10):796-799; 1975.

The ultrastructure of the hepatocytes of a 5-yr-old girl with alpha-1-antitrypsin (AAT) deficiency with the genotype Pi$_{--}$ was studied to confirm the hypothesis that AAT aggregates (which are characteristic of AAT deficiency with the genotype PiZZ) should be absent in the AAT deficiency with genotype Pi$_{--}$. The ultrastructural appearance of the liver on light microscopy was normal and no reaction with anti-AAT antibodies labeled with peroxidase was detected by either light or electron microscopy. The normal appearance of the endoplasmic reticulum in this AAT deficiency with Pi$_{--}$ genotype is compatible with the hypothesis that in this variant, synthesis of AAT is completely, or nearly completely, absent. An alternative hypothesis is presented that an abnormal AAT is produced by the liver and secreted into the plasma, but disappears rapidly from the plasma.

0490 SYMPTOMATIC HEPATIC DISEASE IN CYSTIC FIBROSIS: INCIDENCE, COURSE, AND OUTCOME OF PORTAL SYSTEMIC SHUNTING. (Eng.) Stern, R. C.; Stevens, D. P.; Boat, T. F.; Doershuk, C. F.; Izant, R. J., Jr.; Matthews, L. W. (2103 Adelbert Road, Cleveland, OH 44106). *Gastroenterology* 70(5):645-649; 1976.

The incidence, course of hepatic disease, and outcome of systemic shunting are described for 15 of 693 patients with cystic fibrosis developing hepatic disease over an 18-yr period. In 13 patients all symptoms were secondary to portal hypertension. Ten had hypersplenism and six had variceal bleeding, including three who developed both conditions. All five patients who survived the initial episode of gastrointestinal bleeding underwent portal systemic shunting. A shunting procedure also was performed on one patient with hypersplenism but no variceal bleeding. No subsequent deterioration of intellectual function occurred in either the shunted or unshunted patients. Only one of the shunted patients showed progression of hepatic disease after surgery. These results suggest that portal systemic shunting is useful in the treatment of bleeding esophageal varices in cystic fibrosis. It is recommended that a sweat test to rule out cystic fibrosis be included in the evaluation of any teenage or young adult patient with unexplained portal hypertension.

0491 ISOLATION AND CHARACTERIZATION OF A NOVEL VITAMIN B_{12}-BINDING PROTEIN ASSOCIATED WITH HEPATOCELLULAR CARCINOMA. (Eng.) Burger, R. L.; Waxman, S.; Gilbert, H. S.; Mehlman, C. S.; Allen, R. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *J. Clin. Invest.* 56(5):1262-1270; 1975.

High levels of a novel vitamin B_{12}-binding protein (hepatoma B_{12}-BP), which were observed recently in plasma obtained from three adolescent patients with hepatocellular carcinoma, were isolated in homogeneous form from the plasma and pleural fluid of two of these patients using affinity chromatography with vitamin B_{12}-Sepharose. The hepatoma B_{12}-BP was determined to belong to the R-type group of B_{12}-binding proteins and was essentially indistinguishable from the recently isolated human milk and saliva R-type proteins in terms of (a) immunologic properties based on immunodiffusion and immunoprecipitation assays, (b) amino acid composition, (c) molecular weight based on amino acid and carbohydrate content, and (d) absorption spectra. Both hepatoma B_{12}-BP's contained more sialic acid and less fucose than the milk and saliva B_{12}-BP's. All four proteins contained similar amounts of galactose, mannose, galactosamine, and glucosamine. Differences in sialic acid content appeared to account for the differences in electrophoretic mobility observed among the four proteins. Differences in total carbohydrate content appeared to account for the differences in apparent molecular weight observed with both gel filtration and sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Tumor tissue from one of the patients contained 10 times as much R-type protein as did normal liver tissue from the same patient. This suggests that synthesis by the tumor is the cause of high levels of R-type protein found in the plasma of certain patients with hepatocellular carcinoma. Plasma survival studies in rabbits indicated that hepatoma B_{12}-BP has a prolonged plasma survival, another important parameter.

0492 ADENOSQUAMOUS CARCINOMA OF THE LIVER.

(Eng.) Barr, R. J.; Hancock, D. E. (Veterans Admin. Hosp., Long Beach, CA 90801). *Gastroenterology* 69(6):1326-1330; 1975.

A rare case of adenosquamous carcinoma of the liver is reported. An 85-yr-old man presented with a 6-month history of weight loss and an enlarged liver. A biopsy demonstrated a squamous cell carcinoma that was presumed to be metastatic with an occult primary. At autopsy, the liver was partially replaced by a focally cystic tumor. Histologically, the neoplasm demonstrated both malignant squamous and glandular components as well as foci of transition between the two. This is in contradistinction to the five previously reported cases of primary hepatic squamous cell carcinomas or tumors containing a squamous component. It is suggested that this neoplasm arose from malignant transformation of squamous metaplasia in a preexisting cholangiocarcinoma.

0493 CONGENITAL HEPATIC FIBROSIS: ASPECTS OF DIAGNOSIS AND SURGICAL MANAGEMENT.

(Eng.) Sokhi, G. S.; Morrice, J. J.; McGee, J. O.; Blumgart, L. H. (Glasgow Royal Infirmary, Glasgow, Scotland). *Br. J. Surg.* 62(8):621-623; 1975.

Case reports were presented for five cases of congenital hepatic fibrosis who underwent portasystemic shunt for portal hypertension. Case I, a girl of 17 yr with a life-long history of hematemesis and iron-deficiency anemia presented with esophageal and fundic varices. Liver function tests were normal and a mesocaval shunt was carried out; recovery was uneventful. Case II, a woman aged 30 yr, was admitted with hematemesis and melena; there was a family history of congenital hepatic fibrosis. Splenectomy and splenorenal anastomosis were carried out after an operative portal venogram revealed a patent portal vein. A gastroenterostomy was performed 7 yr later for a duodenal ulcer. Two yr later, the patient presented with hematemesis, ascites, abnormal liver function tests, and varices of the esophagus and body of the stomach. Following mesocaval shunt the patient died from pulmonary edema and bronchopneumonia. Case III, a woman of 61 yr, had a history of hematemesis. On admission she was semicomatose with an extensive clotting defect and an intact and patent portal vein; there was no evidence of a previous portacaval shunt. Splenectomy and splenorenal shunt were performed and a liver biopsy confirmed the diagnosis of congenital hepatic fibrosis. The patient developed hypotension, acute left ventricular failure, and anuria and died 24 hr after surgery. The fourth case, an 11-yr-old boy presented with hematemesis. Laparotomy at age 22 yr showed a thrombosed portal vein. A liver biopsy demonstrated congenital hepatic fibrosis. The patient died 4 yr later and after five episodes of hematemesis and melena. The last case, a man of 29 yr, was admitted with hematemesis and hepatosplenomegaly. At laparotomy, portal pressure was 32 cm H_2O. Splenectomy and splenorenal anastomosis were performed and the liver biopsy showed congenital hepatic fibrosis. These cases illustrate a good prognosis for congenital hepatic fibrosis if there is early correction of portal hypertension.

0494 SERUM PHOSPHOLIPIDS IN BILHARZIAL HEPATIC FIBROSIS AND CHRONIC ACTIVE HEPATITIS.

(Eng.) Gabr, Y.; Mahfouz, M. (Medical Res. Inst., Alexandria Univ., Alexandria, A.R. Egypt). *Acta Biol. Med. Ger.* 34:1827-1833; 1975.

Serum phospholipid fractions were quantitated by thin layer chromatography in 33 patients with bilharzial hepatic fibrosis, 11 patients with chronic active hepatitis, and 25 normal subjects to compare changes in serum lipid pattern in bilharzial patients and patients with chronic active hepatitis. In bilharzial hepatic fibrosis, the total serum phospholipid level showed a significant drop, while in chronic active hepatitis it was significantly elevated above the normal level of the controls. In both groups of patients, the percentage of phospholipids analyzed as lecithin was significantly elevated. Sphingomyelin tended to be within the normal range of controls, while the percentages of lysolecithin and cephalin fractions were significantly decreased. The increase in the relative percentage of lecithin with the simultaneous decrease of the relative percentage of lysolecithin was referred to the decrease of the lecithin-cholesterol acyl transferase enzyme activity in the plasma of these patients. The authors suggest that the low lipid levels observed in bilharzial patients may be due to the poor condition of these patients or a reflection of decreased synthesis when liver function is impaired. Furthermore, the elevation of lecithin and sphingomyelin concentrations in chronic hepatitis may be a result of intrahepatic obstruction which may lead to biliary retention and the accumulation of phospholipids in the blood.

LIBRARY U. OF I.

0495 ESTIMATION OF HEPATIC BILIRUBIN UDP-GLUCURONYL TRANSFERASE IN PATIENTS WITH NONCIRRHOTIC PORTAL FIBROSIS AND LIVER DISEASE: SIGNIFICANCE AND LIMITATIONS.

(Eng.) Datta, D. V.; Nair, R.; Nair, C. R. (Postgraduate Inst. Medical Education Res., Chandigarh-160011, India). *Am. J. Dig. Dis.* 20(10):961-967; 1975.

Hepatic bilirubin UDP-glucuronyl transferase was assayed in percutaneous needle biopsy samples from patients with infectious hepatitis (9), postnecrotic cirrhosis (14), Gilbert's disease (3), noncirrhotic portal fibrosis (NCPF, 10), granuloma of the liver (4), extrahepatic portal vein obstruction (5), and 10 control subjects. A micromethod employing diazotized ethylanthranilate was used to estimate the enzyme content in small amounts of tissue. Patients with cirrhosis and infectious hepatitis revealed normal bilirubin transferase levels, whereas those with Gilbert's disease showed significantly low enzyme levels. Many patients with NCPF, 3/5 with extrahepatic portal vein obstruction, and all patients with granulomatous involvement of the liver demonstrated significantly low levels. This low activity was not associated with hyperbilirubinemia. The authors suggest that the low hepatic-enzyme activity in noncirrhotic portal fibrosis may be due to sparse smooth endoplasmic reticulum and emphasize that serum bilirubin may remain normal with very low hepatic-enzyme activity. Although induction of the microsomal enzyme bilirubin transferase was observed following phenobarbitone administration (180 mg twice a day for 10 days) in NCPF, this was not apparent in patients with cirrhosis, possibly due to maximal enzyme induction having been achieved by endogenous substrate. The results confirm previous findings regarding normal enzyme activity in cirrhosis and infectious hepatitis, and low enzyme activity in Gilbert's disease.

0496 THE HEPATIC LESION IN REYE'S SYNDROME.

(Eng.) Bove, K. E.; McAdams, A. J.; Partin, J. C.; Partin, J. S.; Hug, G.; Schubert, W. K. (Children's Hosp. Res. Foundation, Elland and Bethesda Ave., OH 45229). *Gastroenterology* 69(3):685-697; 1975.

The hepatic lesion in Reye's syndrome was studied by light microscopy of sequential needle biopsies from 49 patients and correlated with the onset of encephalopathy. Histochemical studies of frozen liver tissue were performed on 37 specimens from 16 patients. The onset of encephalopathy was determined from information supplied by parents. Glycogen content of hepatocytes was assessed in PAS-stained paraffin sections, and was used to categorize the severity of hepatic lesions. Mild glycogen depletion (type I) was either diffuse or exhibited slight periportal accentuation. Moderate glycogen depletion (type II) usually showed total loss in the periportal zone with considerable glycogen retention in the centrilobular region. In seven patients with severe glycogen depletion (type III) there was no trace of stainable glycogen in any region. Total glycogen depletion was never seen in cases with type I or type II lesions. Biochemical analysis of hepatic glycogen content in eight samples less than 24 hr after onset showed that two of three patients with less than 2%/mg liver wet weight (lower limit of normal) died, but all five patients with glycogen values within the normal range recovered. Glycogen replenishment occurred rapidly as patients recovered. The severity of the diffuse microvesicular steatosis was best seen in frozen sections stained for lipid content within 48 hr after onset of encephalopathy. Histochemical studies involving hydrogen or electron transport in hepatic mitochondria demonstrated that the lesion was attributable to mitochondrial injury. The authors suggest that investigation of a specific injury to the tricarboxylic acid cycle or electron transport system is warranted.

0497 FETAL PROGNOSIS IN OBSTETRIC HEPATOSIS.

(Eng.) Laatikainen, T.; Ikonen, E. (Univ. Central Hosp., Haartmaninkatu 2, 00290 Helsinki 29, Finland). *Ann. Chir. Gynaecol. Fenn.* 64(3):155-164; 1975.

Fetal prognosis was studied in 116 women with obstetric hepatosis. The fetus was monitored in 88/116 women by amnioscopy, by oxytoxin challenge test on alternate days, by estriol excretion in maternal 24-hr urine twice a week, and by estimation of the fetal biparietal diameter weekly. In 38% of the pregnancies, signs of fetal distress were found (abnormal heart rate or heart rate pattern, and/or meconium-stained amniotic fluid). These led to increased frequencies of induction of labor and of Caesarean sections as compared with an age, parity-distribution, matched control group. There was a 7.6% increase in the occurrence of twin pregnancies in the hepatosis series. There were 4 intrauterine and 8 perinatal losses of 125 infants born to hepatosis mothers. These observations demonstrate an increased risk for the fetus in pregnancies complicated by obstetric hepatosis. Amnioscopy and fetal heart rate recording during the delivery and oxytocin challenge test were found to be valuable in monitoring the fetal condition. Estriol determinations were of limited value in the predictive assessment of fetal distress in hepatosis, possibly due to impurities disturbing the determinations or to changed estrogen metabolism in cholestasis.

0498 LIVER BIOPSIES FROM PSORIATICS RELATED TO METHOTREXATE THERAPY: 1. FINDINGS IN 123 CONSECUTIVE NON-METHOTREXATE TREATED PATIENTS.

(Eng.) Nyfors, A.; Poulsen, H. (Dept. Dermatology, Finsen Inst., DK-2100 Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand. Sect. A.* 84(3):253-261; 1976.

Morphological features of liver biopsies taken from 113 patients (62 men, 61 women) with severe untreated psoriasis who were referred for methotrexate (MTX) therapy were compared with clinical data. Liver biopsies disclosed pathological histology (mainly fatty change and/or nonspecific reactive hepatitis) in 51% of these patients. The incidence of pathological liver histology did not statistically correlate with psoriasis parameters uch as duration and extent. However, statisticaly significant correlations (p<0.0001) were found etween the frequency of pathological liver histlogy and other factors such as age, obesity, and aily alcoholic intake. Comparison of liver histlogy with SGOT values at the time of liver biopsy howed that while the diagnostic specifity of his test was high (1.00), the diagnostic sensitivty was low (0.17). The authors conclude that ormal values of SGOT should not be relied upon to ndicate all types of liver pathology. Therefore, "risk index" indicating the probability of pathoogical liver histology was developed. To elucidate liver histology and particularly to rule out ibrosis and cirrhosis, a liver biopsy should be erformed in every psoriatic patient with a low core in the risk index prior to beginning MTX herapy.

499 LIVER BIOPSIES FROM PSORIATICS RELATED TO METHOTREXATE THERAPY: 2. FINDINGS EFORE AND AFTER METHOTREXATE THERAPY IN 88 PAIENTS. A BLIND STUDY.

(Eng.) Nyfors, A.; Poulen, H. (Dept. Dermatology, Finsen Inst., DK-2100 openhagen, Denmark). *Acta Pathol. Microbiol. Scand. ect. A.* 84(3):262-270; 1976.

xperiments were conducted to evaluate and compare istological findings in liver biopsy specimens rom 88 patients with severe psoriasis before and fter methotrexate (MTX) therapy, and to correlate ossible changes in liver histology with MTX therapy. MTX was given for an average of 26 months as single weekly, p.o. dose of a maximum 25 mg. The ean cumulative dose was 1733 mg (range 175-4590 ng). A statistically significant increase (p<0.0001) in the number of pathological post-MTX liver biopsies was found. Of the 88 patients, 6 developed cirrhosis and 5 others developed fibrosis during MTX therapy. There was no statistically significant correlation between the number of pathological post-MTX liver biopsy findings in the 88 patients and the cumulative dose or duration of MTX therapy or the admitted alcoholic intake during therapy. Cirrhosis and fibrosis did not develop more frequently in pathological than pre-MTX liver histologies. The liver damage appeared to be due to a multifactorial interaction of straining factors on the liver during MTX therapy. The following precautions for the treatment of psoriasis with MTX are suggested: (a) MTX therapy should be used only in disabling cases, (b) a pre-MTX liver biopsy and repeat liver biopsies at regular intervals of 6 months to 1 yr should be performed, and (c) alcohol should be prohibited, and frequent inquiries should be made about the patient's alcoholic intake.

0500 HEPATITIS AND BILIARY CIRRHOSIS IN RHEUMATOID ARTHRITIS.

(Eng.) van Berge Henegouwen, G. P.; Oomen, H. A. P. C.; Boersma, J. W.; Bronkhorst, F. B.; Brandt, K.-H. (Mayo Clinic, Mayo Foundation, Rochester, MN 55901). *Neth. J. Med.* 18(1):1-11; 1975.

Data on 13 patients with rheumatoid arthritis are presented of whom 7 had nonspecific liver lesions, 3 had chronic liver disease suggestive of primary biliary cirrhosis, and 3 had concomitant hepatic lesions. Based on combined clinical, serological, and histological data, the patients were divided into three groups. The first group included three patients showing disturbed liver function unrelated to rheumatoid arthritis: one patient had acute hepatitis and was HBAg positive; the second had extrahepatic obstruction due to gallstones in the common bile duct, and the third patient had hepatic cirrhosis, probably as a sequela to serum hepatitis 10 yr before. The second group comprised the seven patients with nonspecific hepatic lesions with liver function disturbances characterized by increased serum alkaline phosphatase and 5-nucleotidase, mostly normal serum bilirubin, and elevated SGPT (in one case). Liver function normalized in all these patients as soon as the exacerbation period of rheumatoid arthritis was ended. The last group included three patients with clinical, biochemical, and histological evidence of cholestasis. Serological and histological features were suggestive of autoimmune liver disease. The authors suggest that an early diagnosis of liver involvement in progressive rheumatoid arthritis could become indicative for a change in treatment of these patients.

0501 SPONTANEOUS RUPTURE OF THE LIVER.

(Eng.) Arnesjo, B.; Bengmark, S.; Ihse, I.; Petersson, B. G.; Tornqvist, H.; Vang, J. (Univ. Hosp., Lund, Sweden). *Acta Chir. Scand.* 141(5): 399-402; 1975.

Four cases (3 women, 1 man; aged 55-78 yr) of previously unsuspected spontaneous rupture of the liver are reported. In all these cases, pathological processes in the liver caused the rupture, i.e., primary hepatoma in three cases and a benign angiomatous tumor in one case. In one case, the diagnosis was not established until autopsy and in three cases at operation. In one of these latter cases, however, the bleeding source was not found until a second surgical exploration. The authors recommend four-quadrant puncture for the diagnosis of spontaneous liver rupture even in patients with only a slight suspicion of intra-abdominal hemorrhage. In cases with a ruptured solitary primary liver tumor, an acute liver resection might be performed. If there are multiple tumors, primary or secondary, simple hemostasis seems to be the treatment of choice.

0502 ON THE DEFECT OF SYNTHESIS [SIC] CERULOPLASMIN IN THE LIVER POLYRIBOSOMES IN WILSON'S DISEASE.

(Eng.) Gaitskhoki, V. S.; Kisselev, O. I.; Moshkov, K. A.; Puchkova, L. V.; Shavlovski, M. M.; Shulman, V. S.; Vacharlovski, V. G.; Neifakh, S. A. (Acad. Medical Sci., Leningrad, USSR). *Biochem. Genet.* 13(9/10):533-550; 1975.

The relative amount of polysome-bound nascent ceruloplasmin (CP) chains in liver biopsies obtained from three hepatolenticular degeneration (HDL, Wilson's disease) patients and non-Wilson's

LIBRARY U. OF I. URBANA-CHAMPAIGN

disease patients (controls) were measured to determine the possible qualitative or quantitative defects in CP synthesis at the levels of polysomes and CP messenger RNA (mRNA). Three immunochemical analyses were applied to the measurement of nascent CP contents: 1) immune precipitation of nascent (polysome-bound) and completed CP polypeptides pulse-labeled in cell-free conditions, 2) identification and quantitation of CP-synthesizing polysomes with the aid of I^{125}-labeled anti-CP antibodies, and 3) immunoadsorption of antibody-polysome complexes on CP gels. Experiments with the I^{125}-immunoglobin binding showed that human liver polysomes consisting of 10-12 monomers are engaged in CP synthesis. In the liver of Wilson's disease patients, the proportion of *in vivo* CP-synthesizing polysomes was sharply (10-20 times) decreased. The decreased amount of nascent CP chains was also demonstrated by immunochemical analysis of labeled polypeptides formed in cell-free preparations from the livers of HLD patients under the conditions of extension and/or completion of *in vivo* preinitiated chains. The lowering of CP concentration in the sera of HLD patients corresponded to the decreased relative amount of liver polysomes involved in CP synthesis. These data support earlier studies on the decrease of intracellular CP content in the liver of Wilson's disease patients. The size of CP-synthesizing polysomes in the liver of HDL patients was the same as in normal human liver, suggesting that the block of CP synthesis in these patients is not due to decreased efficiency of CP mRNA readout, but to a decreased amount of translatable CP mRNA. The underlying primary genetic defect may be localized either in the CP structural gene or in some other gene related to the control of CP synthesis.

0503 UREA SYNTHESIS AFTER ORAL PROTEIN INGESTION IN MAN. (Eng.) Rafoth, R. J.; Onstad, G. R. (Hennepin County Medical Center, Minneapolis, MN 55415). *J. Clin. Invest.* 56(5):1170-1174; 1975.

Hourly urea production and corresponding serum amino acid concentrations after the ingestion of single protein meals (60, 120, and 240 g of protein) were evaluated in 18 normal subjects and in 8 patients with liver disease to assess hepatic functional capacity. In normal subjects, the relation between urea production and serum amino acid concentration was linear; urea production (mg urea nitrogen/kg lean body mass) = 6.3 times the serum amino acid concentration (mg amino acid nitrogen/100 ml) minus 20.5 (SE of the estimate). Variation of protein intake from 50 to 150 g/day for 3 days before testing did not change this relation. The patients demonstrated impairment of urea synthesis proportional to the clinical severity of their liver disease. The results indicate, in contrast to previous studies, that within the range of serum amino acid concentration achieved, that concentration, rather than the liver's synthetic ability, was the limiting factor in urea production.

0504 HEMOBILIA FOLLOWING PERCUTANEOUS LIVER BIOPSY. (Eng.) Ball, T. J.; Mutchnik, M. G.; Cohen, G. M.; Burrell, M. (Yale-New Haven Hosp., 333 Cedar Street, New Haven, CT 06510). *Gastroenterology* 68(5):1297-1299; 1975.

A 26-yr-old male was admitted with gastrointestinal hemorrhage 1 day after being discharged with a diagnosis of sarcoidosis. A needle liver biopsy was performed for tissue diagnosis 3 days prior to admission and no apparent bleeding had occurred. A gastric aspirate on the second admission contained blood while the urine contained bilirubin; the hematocrit dropped from 39% to 29%. After transfusion (7 U of blood in the first 24 hr), selective celiac and superior mesenteric angiography failed to show bleeding. Filling defects were seen on retrograde cholangiography. Elevated SGOT, serum alkaline phosphatase, and serum bilirubin returned to normal values. The patient was free of pain after the second day. Follow-up for 9 months showed no further evidence of bleeding. The authors suggest that selective mesenteric angiography is the best diagnostic procedure for hemobilia following percutaneous liver biopsy.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

0525 A NEW APPROACH TO QUANTITATION OF THE VARIOUS SOURCES OF BILIRUBIN IN MAN. (Eng.) Berk, P. D.; Blaschke, T. F.; Scharschmidt, B. F.; Waggoner, J. G.; Berlin, N. I. (Digestive Diseases Branch, NIAMDD, Bldg. 10, Natl. Inst. Health, Bethesda, MD 20014). *J. Lab. Clin. Med.* 87(5):767-780; 1976.

Isotopic measurements of plasma bilirubin turnover (BRT), total RBC volume (TRCV), and RBC survival were used to estimate excess bilirubin synthesis in 26 normal volunteers and 35 patients with various hepatic and/or hematologic disorders. The quantity of bilirubin derived from RBC degradation (BR_{RBC}) was calculated from TRCV and the mean RBC life-span,

LIBRARY U. OF I.

and the difference between BRT and BR_{RBC}, designated "excess bilirubin synthesis (EBS)," was considered to represent the quantity of bilirubin derived from the processes responsible for early labeled pigment peaks. In normal volunteer subjects, EBS averaged 1.0 mg/kg/day, and accounted for 25% of daily bilirubin turnover. The results derived by this approach exceeded the range estimated from analysis of "early labeled peak" data. Further analysis of the data in terms of a simple model of bilirubin sources was compatible with the hypothesis that EBS consists of an essentially constant component, averaging 0.8 mg/kg/day, presumably derived principally from the liver, and a second component which varies with the erythropoietic rate. The authors conclude that in normal man the liver may contribute the major fraction of EBS.

0526 BILIRUBIN AND PARANITROPHENOL GLUCURONYL TRANSFERASE ACTIVITIES AND ULTRASTRUCTURAL ASPECT OF THE LIVER IN PATIENTS WITH CHRONIC HEMOLYTIC ANEMIAS.

(Eng.) Auclair, C.; Feldmann, G.; Hakim, J.; Boivin, P.; Boucherot, J.; Troube, H. (Faculte de Medecine Bichat-Beaujon, Paris VII, Hopital Beaujon 100, boulevard du General Leclerc, 92110 Clichy, France). *Biomed. Express (Paris)* 25(2):61-65; 1976.

The hepatic ultrastructure and hepatic bilirubin (Bil-GT) and paranitrophenol (PNP-GT) glucuronyl transferase activities were studied in 20 patients with chronic hemolytic anemia (HA) and in 5 with an aplastic anemia. In chronic HA, the hepatocytes of five of eight patients showed mitochondrial abnormalities in structure (paracrystalline inclusions), size (giant mitochondria), and shape (irregular mitochondria). There was a decrease of Bil-GT activity in 80% of the 20 patients with HA. No connection was observed between HA etiology and the degree of enzymatic activity decrease. No deficiency of PNP-GT was observed in HA. In chronic aplastic anemias, there was apparently no modification of either Bil-GT or PNP-GT activity. It is concluded that Bil-GT is often decreased in HA and that neither Bil-GT measurement nor the hepatic ultrastructure distinguish chronic HA from Gilbert's syndrome.

0527 PROLONGED SURVIVAL IN THREE BROTHERS WITH SEVERE TYPE 2 CRIGLER-NAJJAR SYNDROME: ULTRASTRUCTURAL AND METABOLIC STUDIES.

(Eng.) Gollan, J. L.; Huang, S. N.; Billing, B.; Sherlock, S. (Royal Free Hosp., Pond St., London, NW3 2Q3, England). *Gastroenterology* 68(6):1543-1555; 1975.

Case reports are presented for three brothers (I, II, and III aged 59, 53, and 55 yr old, resp.) with severe type 2 Crigler-Najjar syndrome and severe jaundice for over 50 yr. One other brother (48-yr-old) had been diagnosed as having Gilbert's syndrome. Phenobarbital therapy (180 mg/day for 7 weeks) in patient I produced a fall in plasma bilirubin concentration from 19.5 to 6.9 mg/100 ml. A low calorie (400 cal/day) diet in patient II produced a rise in plasma unconjugated bilirubin from 22.5 to 30 mg/100 ml. Phenobarbital therapy (180 mg/day) after restoration to normal caloric intake produced a fall in plasma bilirubin to 4.0 mg/100 ml in 14 days. Electron microscopy of pretreatment liver biopsy specimens from two of the patients showed marked hypertrophy and hyperplasia. Phenobarbital treatment produced further hypertrophy of the smooth endoplasmic reticulum and minor changes in bile canaliculi. The smooth endoplasmic reticulum appeared to be functionally hypoactive with respect to glucuronyl transferase activity. Patient III received the low calorie diet for 3 days in which time plasma bilirubin rose from 20.0 to 26.5 mg/100 ml. After addition of 1200 ml of 50% dextrose i.v. (2400 cal/day) to the 400-calorie diet, plasma bilirubin increased to 30 mg/100 ml in 3 days and returned to normal values by 5 days. Phenobarbital (180 mg/day) produced a reduction to 4.0 mg/100 ml within 14 days. Fasting and i.v. dextrose maintenance were resumed 4 weeks after beginning phenobarbital therapy. Plasma bilirubin increased from baseline to 6 mg/100 ml with the low calorie diet and was maintained with i.v. dextrose, but fell from 8.3 to 4.8 mg/100 ml within 24 hr of returning to a normal diet. These data suggest that the hyperbilirubinemia of fasting does not depend on caloric deficiency *per se*, and that either the route of caloric administration or the type of nutrient may influence the level of unconjugated hyperbilirubinemia.

0528 ABNORMAL HEPATIC TRANSPORT OF INDOCYANINE GREEN IN GILBERT'S SYNDROME.

(Eng.) Martin, J. F.; Vierling, J. M.; Wolkoff, A. W.; Scharschmidt, B. F.; Vergalla, J.; Waggoner, J. G.; Berk, P. D. (Natl. Inst. Arthritis, Metabolism, Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *Gastroenterology* 70(3):385-391; 1976.

The plasma fractional disappearance rate of graded doses of indocyanine green (k_{ICG}, min^{-1}) and the absolute hepatic ICG removal rate (V_{ICG}, mg/kg/min) were determined in 26 patients (21 men and 5 women) with Gilbert's syndrome (GS) and in 19 normal control volunteers following i.v. administration of dye (0.5, 2.0, 3.5, and 5.0 mg/kg). The diagnosis of GS was based on studies of radiobilirubin kinetics in all cases and on liver biopsy in 22 cases. The patients were further classified into three subgroups, based on patterns of BSP kinetics, as follows: GS I (15 patients) had normal BSP metabolism, GS II (5 patients) had a defect in BSP metabolism beyond the stage of initial hepatic uptake, and GS III (6 patients) had a defect in the initial hepatic uptake of BSP. Both k_{ICG} and V_{ICG} were significantly reduced compared to normal controls in the GS III group, but did not differ significantly from normal in the GS I and GS II groups. Michaelis-Menten analysis of the data indicated that V_{max} for ICG uptake in the GS III group (1.2 ± 0.6 mg/min/kg) was significantly reduced compared to the established normal value of 3.6 ± 0.6 mg/min/kg; ($p<0.01$). For all 26 GS patients, there was a highly significant correlation ($p<0.01$) between kICG and the fractional hepatic uptake rate for BSP. These studies confirm previous work indicating that patients with GS constitute a heterogeneous population with regard to defects in hepatic organic anion transport, some of the defects not being attributable to glucuronyl transferase deficiency.

0529 COMPARISON OF THE EFFECTIVENESS OF PHOTOTHERAPY AND EXCHANGE TRANSFUSION IN THE MANAGEMENT OF NONHEMOLYTIC NEONATAL HYPERBILIRUBINEMIA. (Eng.) Tan, K. L. (Dept. Paediatrics, Univ. Singapore, Republic Singapore). *J. Pediatr.* 87(4): 609-612, 1975.

The relative effectiveness of phototherapy and exchange transfusion for nonhemolytic neonatal hyperbilirubinemia was compared in 52 infants; 26 were given phototherapy and the other 26 (closely matched) received exchange transfusion. Although the exchange transfusion achieved an immediate reduction of bilirubin level, the "rebound" was rapid and tended to offset this reduction. The more gradual and steady effect of phototherapy resulted in a significantly lower serum bilirubin level at 1, 2, and 3 days after commencement of therapy; the rebound after phototherapy was small. Phototherapy was more effective than exchange transfusion in achieving prolonged reduction of bilirubin levels for nonhemolytic hyperbilirubinemia. With more efficient lamps delivering more energy in the desired spectrum, it seems feasible to treat hyperbilirubinemia of whatever etiology with this safer and more convenient form of therapy.

0530 FACTORS AFFECTING THE INCREASING INCIDENCE OF SEVERE NON-HAEMOLYTIC NEONATAL JAUNDICE. (Eng.) Sims, D. G.; Neligan, G. A. (Princess Mary Maternity Hosp., England). *Br. J. Obstet. Gynaecol.* 82(11):863-867; 1975.

In view of conflicting evidence about the possible causes of the increasing incidence of neonatal hyperbilirubinemia, retrospective analyses were carried out among babies born during 6 months of 1974. Preliminary analysis confirmed the overriding importance of preterm birth (before 37 weeks), but only 1 of 17 such cases could be attributed to ill-judged artificial induction of labor. For the main analysis, the incidence of 8 possibly relevant antecedent factors was compared in 46 cases of hyperbilirubinemia (unconjugated bilirubin > 15 mg/100 ml in term babies and > 13 mg/100 ml in some preterm babies) and in 92 controls matched for sex and gestational age. Induction of labor by "primary" oxytocin infusion and artificial rupture of the membranes was significantly more common in the index cases ($p<0.01$), but there was no difference in the incidence of "secondary" oxytocin, used to accelerate spontaneous labor. Evidence of uterine unresponsiveness suggests that the natural onset of labor was being anticipated by at least some days in many of the index cases and this could prevent the natural "priming" of the fetal enzyme systems. An excess of epidural analgesia in the mothers of the index cases was probably due to its association with the need for pain relief during "primary" oxytocin infusions. The higher incidence of postnatal weight loss in the index cases presumably contributes to the hyperbilirubinemia.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

0536 IMMUNOLOGIC STUDIES IN AMOEBIC LIVER ABSCESS. (Eng.) Ravi, V. V.; Mithal, S.; Malaviya, A. N.; Tandon, B. N. (All-India Inst. Medical Sciences, Ansari Nagar, New Delhi-110016, India). *Indian J. Med. Res.* 63(12):1732-1736; 1975.

The indirect hemagglutination (IHA) test for amebiasis was carried out in 14 patients with amebic liver abscess using sera and aspirate from abscess to determine if false-negative tests in serum can be avoided by simultaneously testing the aspirate. In addition, the cause of negative IHA test for amebiasis in patients with proven amebic liver abscess was studied by analysis of nutritional factors and serum albumin. Six of the 14 cases showed a positive reaction using aspirate, while 12 of the 14 cases were positive using serum. When positive, the titer in the aspirate was equal to or lower than the titer in the corresponding serum. Complement (C_3) levels in the serum and in the aspirate were also estimated. In all patients, the C_3 levels in the aspirate were significantly lower than those in the corresponding serum. The nutritional study, a detailed questionnaire of dietetic history, and serum albumin determination did not reveal any difference between the seronegative and -positive patients. The results demonstrate for the first time positive IHA tests in the aspirate of patients with amebic liver abscess.

0537 SERUM COBALT-ACTIVATED ACYLASE AND γ-GLUTAMYL TRANSPEPTIDASE ACTIVITIES IN TOXIC HEPATITIS. (Eng.) Szczeklik, A.; Wiernikowski, A.; Musial, J.; Wozny, E. (Copernicus Sch. Medicine, Krakow, Poland). *Gut* 16(8):626-629; 1975.

In a study of 69 patients with acute intoxication in whom liver injury was suspected, the determination of serum cobalt-activated acylase appears to by of value in the diagnosis of acute liver injury. Among 22 of 26 patients poisoned with cytotoxic amanita mushrooms, *A. phalloides* was detected in 17 and *A. pantherina* in 5. In these 26, and in 11 others poisoned with hepatotoxic chemicals, serum acylase activity was marked. The activity of the enzyme showed a positive correlation with that of serum transaminases, reached the highest levels on the patient's admission to hospital, and fell rapidly to undetectable levels in a few days. Slight acylase activity was observed in the majority of patients intoxicated with drugs or carbon monoxide but was not seen in sera of those poisoned with nonamanita mushrooms who showed no signs of liver injury. Unlike acylase, the serum activity of γ-glutamyl transpeptidase remained unchanged over the first days of acute toxic hepatitis. The authors suggest that the determination of serum cobalt-activated acylase might be of value in the diagnosis of acute liver injury.

0538 GUIDELINES FOR HISTOLOGICAL EVALUATION OF DRUG-INDUCED LIVER DAMAGE. (Ger.) Bianchi, L.; De Groote, J.; Desmet, V.; Gedigk, P.; Korb, G.; Popper, H.; Poulsen, H.; Scheuer, P. J.; Schmid, M.; Thaler, H.; Wepler, W. (Institut Pathologie, Universitat, CH-4056 Basel, Schonbeinstr. 40, Switzerland). *Dtsch. Med. Wochenschr.* 100(35):1746-1750; 1975.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

0540 DETECTION OF HB_sAg IN FIXED LIVER TISSUE--USE OF A MODIFIED IMMUNOFLUORESCENT TECHNIQUE AND COMPARISON WITH HISTOCHEMICAL METHODS. (Eng.) Portmann, B.; Galbraith, R. M.; Eddleston, A. L. W. F.; Zuckerman, A. J.; Williams, R. (King's Coll. Hosp., Medical Sch., Denmark Hill, London, England). *Gut* 17(1):1-9; 1976.

A modified immunofluorescent technique was used to detect hepatitis B surface antigen (HB_sAg) in formalin-fixed liver tissue. This method allowed retrospective examination of paraffin section and avoided the need to split the sample at the time of biopsy. In a series of 146 seropositive and 74 seronegative patients with a variety of liver disorders, hepatocytes positive for HB_sAg were found in only 1 of 55 patients with acute hepatitis type B, whereas larger numbers of positive cells were seen in all 22 healthy carriers of the antigen. In the 69 patients with chronic persistent or chronic aggressive hepatitis, the frequencies of positive biopsies were 86% and 85%, resp. The positive cells in these cases were, in comparison with healthy carriers of HB_sAg, much fewer in number and were scattered in random fashion throughout the lobule rather than occurring in discrete clumps or sheets. It is concluded that the variation in the intrahepatic expression of HB$_s$Ag may reflect differences in the immune response to hepatitis B viral antigens.

0541 INHIBITION OF MACROPHAGE MIGRATION IN RESPONSE TO HEPATITIS B$_S$ ANTIGEN. (Eng.)

Howlett, S. A.; McGuigan, J. E. (Univ. Florida, Coll. Medicine, Gainesville, FL 32611). *Gastroenterology* 69(4):960-964; 1975.

The macrophage inhibition test was used to detect the presence or absence of cell-mediated immunity to hepatitis B antigen (HB$_s$Ag) in 16 patients with acute viral hepatitis (11 were serologically positive and 5 serologically negative) and 15 patients with chronic aggressive hepatitis (10 serologically negative and 5 persistently serologically positive for the HB$_s$Ag). The results were compared with those obtained in 11 normal control subjects and 7 patients with other liver diseases (5 with alcoholic hepatitis and 2 with primary biliary cirrhosis). Inhibition of macrophage migration in response to purified HB$_s$Ag was demonstrated in serologically positive patients with acute viral hepatitis. Inhibition was not observed in patients serologically negative for HB$_s$Ag or in those patients with other liver diseases. Positive inhibition was observed in 2/11 control subjects. Chronic aggressive hepatitis patients, whether serologically negative or positive for HB$_s$Ag, were also found to have positive macrophage migration inhibition tests (14/15 patients). These results suggest that cell-mediated immunity against this antigen occurs concomitantly with the illness, and may be important in its pathogenesis. This is the first report of detection of macrophage inhibition in response to HB$_s$Ag in patients with acute viral hepatitis and chronic aggressive hepatitis.

0542 HEPATITIS B SURFACE ANTIGEN IN THE SERUM OF INFANTS AFTER DELIVERY FROM ASYMPTOMATIC CARRIER MOTHERS. (Eng.)

Okada, K.; Yamada, T.; Miyakawa, Y.; Mayumi, M. (Okubo Municipal Hosp., Shinjuku-ku, Tokyo, Japan). *J. Pediatr.* 87(3):360-363; 1975.

A study was undertaken to identify hepatitis B surface antigen (HBsAg) in cord blood and in later serum specimens from infants delivered of mothers who were asymptomatic carriers of HBsAg. A survey of the sera of 5,993 pregnant women in Tokyo revealed 139 asymptomatic carriers (2.3%), essentially the same as that of a control population of comparable age (2.2%). None of the 59 specimens of cord blood of their newborn infants was positive for HBsAg, according to an immune adherence hemagglutination assay. In 11 mother-child pairs in whom follow-up was possible for more than 7 months, HBsAg was detected in the sera of 8 infants within the first 6 months after birth, with antigenemia persisting throughout the observation period; antigenemia was not detected in the remaining 3. The subtype of HBsAg was identical for each mother-child pair. The antigen was detected in the sera of two of the infants after appropriate incubation periods of 123 and 133 days, resp., whereas in others it was detected as early as 5 and 13 days after delivery.

0543 'GROUND-GLASS' HEPATOCYTES. (Eng.)

Cohen, C. (South African Inst. Medical Res., Johannesburg, South Africa). *S. Afr. Med. J.* 49(34):1401-1403; 1975.

The case reports of two patients are presented in whom "ground-glass" hepatocytes were noted in hematoxylin and eosin-stained, formalin-fixed, paraffin-embedded specimens on liver biopsy. Case 1, a 25-yr-old hepatitis B antigen (HBAg)-positive woman, presented with gross, blood-stained ascites and macronodular cirrhosis. At laparotomy, her liver was firm and irregularly nodular. In focal clusters were ground-glass hepatocytes with eosinophilic, granular, glassy cytoplasm displacing the nucleus to the periphery of the cell. Brown aggregates of HBAg were seen (with orecin stain) in the cytoplasm near the nucleus of these ground-glass hepatocytes. Case 2, a 2-week-old male infant, presented with marked jaundice (total serum bilirubin was 27 mg/100 ml, 20 mg unconjugated). The patient was treated with phototherapy and 6 mg phenobarbitone/8 hr for 6 days but without response. A needle biopsy specimen of the liver was examined when the patient was 3 weeks old; there was evidence of hepatitis with scarring within the parenchyma. Diffusely distributed throughout the specimen and giving a "cobblestone" appearance were ground-glass hepatocytes with most nuclei central in situation. The cytoplasm did not stain with orecin, indicating that the ground-glass condition was drug-induced. In HBAg-positive patients, ground-glass hepatocytes are focally distributed in clusters. The nucleus is often eccentric with the ground-glass cytoplasm arranged in a peripheral rim. The cytoplasm stains dark-brown with orecin and blue with chromotrope aniline blue. Positive immunofluorescence with a fluorescein-conjugated antibody to hepatitis B surface antigen and the presence of intracisternal filaments and spheres indicate the presence of surface antigen in the proliferated smooth endoplasmic reticulum. These features are absent in drug-induced ground-glass hepatocytes. The author concludes that the modified orcein stain is useful for the demonstration of hepatitis B surface antigen in the cytoplasm of liver cells of HBAg carriers.

0544 IMMUNOLOGICAL ASPECTS OF HEPATITIS B VIRUS INFECTION. (Eng.)

Edgington, T. S.; Chisari, F. V. (Scripps Clinic Res. Foundation, 476 Prospect St., La Jolla, CA 92037). *Am. J. Med. Sci.* 270(2):213-227; 1975.

The various immunological aspects of hepatitis B virus (HBV) infection are reviewed. HBV infection of man and chimpanzees is associated with diffuse hepatocellular infection and variable manifestations of disease that may not only reflect the character of the host immune response, but also depend upon the differences in the cellular biology of this minimally cytopathic or noncytopathic agent. It

LIBRARY U. OF I.

appears that the presence of hepatocellular injury and the course of disease are related to the presence of viral antigens in hepatocytes or to the specific pattern of genome expression. HBV infection is typically associated with both humoral and cellular immune responses to viral and hepatocellular antigens. Whereas cellular effector systems may be responsible for immunologically mediated hepatocellular injury, the patterns of viral antigen synthesis and expression may be modulated by the humoral immune response. Aberration of lymphocyte function occurs during acute hepatitis type B. Thymus-derived lymphocyte function is abnormal and is associated wiht persistent humoral supression of T lymphocyte function during the development of the chronic carrier state. Extrahepatic disease appears attributable to the formation and deposition of hepatitis B surface antigen-antibody complexes. Information of the biology and immunology of HBV and other viruses was integrated into a hypothesis to explain the pathogenesis of injury and events associated with persistent infection. Hepatocellular injury and persistence of viral synthesis may be determined by the regulation of synthesis and hepatocyte surface expression of viral and cellular antigens as well as by the specificity and character of the host immune response. Termination of HBV infection is viewed as suppression of viral genone rather than eradication of infected cells. The authors conclude that although immune complex injury does occur in association with HBV infection, it is of secondary importance in regard to the frequency and severity of disease. If the humoral antibody response is of benefit to the host, the deleterious aspects of persistent immune complex formation may lie not so much in the injury produced by immune complexes as in the failure of the immune response, including humoral antibody, to adequately suppress viral synthesis, interrupt the pathogenetic processes, and promote recovery.

0545 ACUTE VIRAL HEPATITIS: A COMPARATIVE STUDY OF CLINICAL, BIOCHEMICAL, MORPHOLOGICAL AND IMMUNOLOGICAL FEATURES IN PATIENTS WITH AND WITHOUT AUSTRALIA ANTIGEN. (Eng.) Nielsen, J. O.; Faber, V.; Poulsen, H.; Christoffersen, P.; Dietrichson, O.; Elling, P.; Iversen, K.; Juhl, E.; Petersen, P. (Kommunehospitalet, Copenhagen, Denmark). *Scand. J. Infect. Dis.* 7(3):173-177; 1975.

The clinical, biochemical, histological, and serological variables of two groups of patients with acute viral hepatitis were compared; one group of 202 patients had detectable Australia (Au) antigen, while the other group (298 patients) was without antigenemia at the time of admission to hospital. Judged by both histological and biochemical criteria, the acute disease was more severe in the 202 patients with Au antigen than in the 298 patients without Au antigen. At the time of admission, the antigen-positive patients had a higher degree of liver cell damage than did the antigen-negative patients. The IgM concentration was significantly higher in the negative than in the positive group. During hospitalization, peak transaminase activity and bilirubin concentrations were significantly higher, and the lowest prothrombin values were significantly lower in the positive patients. It appears that the differences between the antigen-positive and antigen-negative groups is due more to qualitative etiological differences between the two groups than to the duration of antigenemia or the time of hospitalization. Thus, the demonstration of Au antigenemia provides not only epidemiological but also relevant clinical information.

0546 HEPATITIS B VIRUS INFECTION IN DENTISTS. (Eng.) Mosley, J. W.; Edwards, V. M.; Casey, G.; Redeker, A. G.; White, E. (John Wesley County Hosp., 2826 S. Hope St., Los Angeles, CA 90007). *N. Engl. J. Med.* 293(15):729-734; 1975.

Viral hepatitis was evaluated as a hazard in general dentistry. Of 1245 practitioners surveyed, 0.9% were positive for hepatitis B surface antigen, and 12.7% were antibody-positive. Of those who had had clinical hepatitis while studying or practicing dentistry, 43% were seropositive. The frequency of evidence for prior infection with hepatitis B virus increased uniformly with increasing years of professional experience. The proportion of seropositive dentists did not vary with geographical region of the United States or size of community. Only 10.5% recognized self-injection among patients who were drug abusers, and their infection rate was not increased. These data indicate an increased frequency of infection with hepatitis B virus among general dentists, and are compatible with relatively uniform endemicity of subtype/*ad* strains of that agent in the general population for several decades.

0547 FOODHANDLER-ASSOCIATED OUTBREAK OF HEPATITIS TYPE A: AN IMMUNE ELECTRON MICROSCOPIC STUDY. (Eng.) Dienstag, J. L.; Routenberg, J. A.; Purcell, R. H.; Hooper, R. R.; Harrison, W. O. (Natl. Insts. Health, Bldg. 7, Bethesda, MD 20014). *Ann. Intern. Med.* 83(5):647-650; 1975.

Immune electron microscopy, was used to study a foodhandler-associated outbreak of hepatitis among 136 naval recruits. In stool specimens collected during the acute phase, 27-nm viruslike hepatitis A antigen particles were seen, but only in patients with icteric hepatitis. Detection was possible in stools collected as early as 10 days before peak serum aminotransferase activity and up to the time of peak enzyme activity, but not thereafter. The immunologic similarity of these viruslike particles to those found in acute phase stools of volunteers inoculated with the MS-1 strain of hepatitis A virus was determined, and an increase in anti-HA was shown between acute and convalescent sera from 25 of the recruits. These data support the view that the MS-1 strain of hepatitis A virus is serologically related to naturally acquired type A hepatitis.

0548 ON THE ROLE OF SEXUAL BEHAVIOR IN THE SPREAD OF HEPATITIS B INFECTION. (Eng.) Szmuness, W.; Much, M. I.; Prince, A. M.; Hoofnagle, J. H.; Cherubin, C. E.; Harley, E. J.; Block, G. H.

(Lab. Epidemiology Virology, Lindsley F. Kimball Res. Inst., New York Blood Center, New York, NY). *Ann. Int. Med.* 83(4):489-495; 1975.

A retrospective study was undertaken to ascertain the role of human sexual behavior in the transmission of hepatitis B infection. Sample 1 of the population studies consisted of 238 spouses of volunteer blood donors who were found to be hepatitis B surface antigen (HB$_s$Ag)-negative (19 of the index-donors were anti-HB$_s$ positive). Sample 2 consisted of 280 spouses (87% were wives) of donors who were persistent carriers of HB$_s$Ag. Sample 3 consisted of 597 patients attending two venereal disease clinics; 272 were either under treatment for syphilis or gonorrhea or had had treatment in the past, while the remaining 325 attended clinics for screening and did not have a history of known venereal infection. Sample 4 consisted of 674 homosexuals (93% male). The frequencies of hepatitis B infections in these four samples were compared with the results of screening by laboratory assays of a random, control sample of 10,000 healthy adults from the same area. All participating persons from the four study samples, as well as a 7% systematic subsample of the 10,000 controls, were surveyed for pertinent sociodemographic and epidemiologic information by a self-administered questionnaire. Screening for HB$_s$Ag was done by radioimmune assay and reverse passive hemagglutination; positive specimens were confirmed by neutralization methods. Screening for anti-HB$_s$ was done by passive hemagglutination. Antigenic determinants were assayed by the hemagglutination inhibition method. There was a significant excess of serologic evidence of hepatitis B infection in two high-promiscuity populations: patients with venereal diseases and their unrelated sexual contacts (15-18%) and male, but not female, homosexuals (37-51%). Spouses of asymptomatic chronic carriers of antigen had a higher prevalence (26-28%) than spouses of noncarriers (10-11%). The prevalence in the former was relatively low when compared with rates seen in other relatives of carriers. The results demonstrate a strong association between serologic evidence of type B hepatitis and patterns of sexual behavior; however, whether or not transmission of hepatitis B virus occurs through vaginal intercourse could not be ascertained.

0549 FATE OF INGESTED HEPATITIS B ANTIGEN IN BLOOD-SUCKING INSECTS. (Eng.)

Newkirk, M. M.; Downe, A. E. R.; Simon, J. B. (Div. Gastroenterology, Queen's Univ., Kingston, Ontario, Canada). *Gastroenterology* 69(4):982-987; 1975.

The fate of ingested hepatitis B antigen (HB$_s$Ag) in two mosquito species (*Aedes aegypti* and *Culey tarsalis)* and two Hemiptera species (*Cimex lectularius* L. and *Rhodnius prolixus*) was compared with the rate of blood meal digestion by these insects. In both mosquito species HB$_s$Ag was detected by radioimmunoassay for only a few hours after ingestion, disappearing well before the time of blood meal digestion. Production of a protease by the mosquito midgut may have been responsible for destruction of the antigen. In contrast, in the bedbug HB$_s$Ag remained detectable throughout a 5-week testing period. Moreover, titers rose during the last week, when blood meal digestion was complete, suggesting possible replication of the antigen. At no time was antigen detected in eggs or feces of any species, but juvenile bedbugs fed HB$_s$Ag when in the fourth or fifth instar stage still contained antigen after molting. The results suggest that bedbugs may potentially be a more dangerous source of hepatitis B transmission than mosquitoes.

0550 ARTICULAR AND CUTANEOUS PRODROMAL MANIFESTATIONS OF VIRAL HEPATITIS. (Eng.)

Segool, R. A.; Lejtenyi, C.; Taussig, L. M. (Arizona Medical Center, Tucson, AZ 85724). *J. Pediatr.* 87(5):709-712; 1975.

Initial presentation with arthritis, arthralgia, and skin rash subsequent to the development of hepatitis is described in three children aged 13-16 yr. In one case, the prodromal symptoms occurred 4 weeks before biochemical or clinical evidence of hepatitis. The serum sickness-like illness tended to subside with the onset of clinically evident liver disease. Hepatitis B surface antigen was detected in the sera of two patients, but free antibody to the antigen was not demonstrable in either one. Serum complement levels were low during the prodromal phase and tended to return to normal values at the onset of extensive liver involvement. The diagnosis of viral hepatitis should be considered in children presenting with polyarthritis, polyarthralgia, and a rash of uncertain etiology.

0551 PERSISTENT HB ANTIGENEMIA: ASSOCIATED CLINICAL MANIFESTATIONS AND HEPATIC LESIONS. (Eng.)

Klatskin, G. (Dept. Internal Medicine, Yale Univ., 333 Cedar St., New Haven, CT 06510). *Am. J. Med. Sci.* 270(1):33-40; 1975.

The clinical, biochemical, and histological features in 9 asymptomatic hepatitis B surface antigen (HB$_s$ Ag) carriers, 15 patients with symptomatic HB$_s$ Ag-positive chronic active hepatitis (CAH), and 29 patients with HB$_s$ antigenemia persistent for 5 months or longer following an acute viral hepatitis attack were compared. These data were contrasted with those of 67 patients with HB$_s$ Ag-negative CAH. The findings were remarkably similar in all groups. However, young males predominated in all three HB$_s$ Ag-positive groups, whereas most HB$_s$ Ag-negative cases of CAH were in middle-aged women. In the latter group, the lesions tended to be more extensive and were more commonly accompanied by smooth muscle antibody, antinuclear antibody and lupus erythematosus cells, and extrahepatic manifestations, such as ulcerative colitis, arthritis, pleurisy and pericarditis. All nine asymptomatic HB$_s$ Ag carriers exhibited hepatic lesions indistinguishable from those of CAH. The hepatic lesions, clinical features, and laboratory findings in antigen-positive CAH may be indistinguishable from those of antigen-positive unresolved viral hepatitis. This observation is consistent with the view that HB virus plays a role in

LIBRARY U. OF I.

the pathogenesis of antigen-positive CAH. The predominance of middle-aged women among patients with antigen-negative CAH, in contrast to the predominance of young males among the antigen-positive patients, and the greater frequency of serological abnormalities and extrahepatic manifestations indicative of an altered immunological response, suggest that the HB virus is not an etiologic factor in many cases of antigen-negative CAH.

0552 HEPATITIS B ANTIGEN IN SPORADIC ACUTE VIRAL HEPATITIS. (Eng.) Anand, P. N.; Dutt, M. (Military Hosp., Jullundur, India). *Indian J. Med. Res.* 63(7):916-922, 1975.

The incidence of hepatitis B antigen (HB-Ag), duration of antigenemia, correlation of severity of disease with SGPT activity, serum bilirubin, and total morbidity were recorded for 144 cases of sporadic viral hepatitis. Hepatitis B antigen was detected by immunoelectroosmophoresis in 46 of 126 patients with acute sporadic viral hepatitis and in 12 of 18 patients with tuberculosis who developed acute viral hepatitis while undergoing treatment. The duration of antigenemia in 35 cases of acute sporadic viral hepatitis, was 4-40 days (mean 22.7 days). In two cases in the tubercular group the antigenemia persisted for 122 and 135 days. High incidence of HB-Ag in the tubercular group and persistent antigenemia in two patients of the same group, may be explained on the basis of altered immunological behavior of the hosts. There was no significant difference in the severity of the disease in the HB-Ag positive and negative group as assessed by SGPT, serum bilirubin, and total morbidity.

0553 GUILLAIN BARRE SYNDROME DURING THE PREICTERIC PHASE OF ACUTE TYPE B VIRAL HEPATITIS. (Eng.) Ng, P. L.; Powell, L. W.; Campbell, C. B. (Outram Rd. General Hosp., Singapore). *Aust. N.Z. J. Med.* 5(4):367-369; 1975.

The authors describe the case of a 54-yr-old man who presented with Guillain Barre syndrome (GBS) during the preicteric phase of acute type B viral hepatitis. The patient had an ascending paralysis of the extremities, albuminocytological dissociation in the cerebrospinal fluid, and biochemical evidence of hepatocellular damage without hyperbilirubinemia. This neurological syndrome has been described infrequently in the clinical course of viral hepatitis, but only once during the prodromal period. The authors conclude that deposition of circulating immune complexes of the hepatitis B surface antigen may be involved in the pathogenesis of GBS, since this mechanism has been implicated in the pathogenesis of arthritis, nephritis, and polyarteritis.

0554 HEPATITIS B ANTIGEN (HB$_s$Ag) AND/OR ANTIBODIES (ANTI-HB$_s$ AND ANTI-HB$_c$) IN FULMINANT HEPATITIS: PATHOGENIC AND PROGNOSTIC SIGNIFICANCE. (Eng.) Trepo, C. G.; Robert, D.; Motin, J.; Trepo, D.; Sepetjian, M.; Prince, A. M. (Laboratoire d'Hygiene Faculte de Medecine, Clinique des Maladies Infectieuses, Hopital de la Croix Rousse, Service de Reanimation, Lyon, France). *Gut* 17(1):10-13; 1976.

Hepatitis B surface antigen (HB$_s$Ag) and antibodies to both the surface and core antigens of the hepatitis B virus (anti-HB$_s$ and anti-HB$_c$) were studied in 64 consecutive cases of fulminant hepatitis to clarify the role of hepatitis B virus and of the immune response in the pathogenesis of fulminant hepatitis. HB$_s$Ag was detected by counterelectrophoresis in 23 patients but by radioimmunoassay in 38. Anti-HB$_s$ was detected by passive hemagglutination in 26, and coexisting HB$_s$Ag and anti-HB$_s$ were found in 16 cases. Using an indirect immunofluorescence technique, anti-HB$_c$ was found in all patients in whom either HB$_s$Ag or anti-HB$_s$ was present. The highest survival rate was observed in patients with no evidence of HBV infection (31.3%) and was lowest in those who had both HB$_s$Ag and anti-HB$_s$ detected simultaneously (6.2%). The prognosis of those who exhibited anti-HB$_s$ only was no better than those with HB$_s$Ag alone. In a further case, transient interruption of the asymptomatic chronic HB$_s$Ag carrier state with seroconversion to anti-HB$_s$ was associated with the development of a fulminant hepatitis syndrome. The results suggest that an unusually strong and rapid immune clearance of HB$_s$Ag may be involved in the pathogenesis of fulminant hepatitis.

0555 FULMINANT HERPES SIMPLEX HEPATITIS IN AN ADULT: REPORT OF A CASE IN RENAL TRANSPLANT RECIPIENT. (Eng.) Anuras, S.; Summers, R. (Dept. Internal Medicine, Univ. Iowa, Iowa City, IA). *Gastroenterology* 70(3):425-428; 1976.

A case of disseminated herpes simplex infection in a 31-yr-old man who was a renal transplant recipient is reported. The patient presented with a unique clinical syndrome: high fever, severe sore throat with buccal and pharyngeal ulcerations, fulminant hepatitis, thrombocytopenia, and leukopenia. The patient died from hepatic failure, disseminated intravascular coagulopathy, and upper gastrointestinal bleeding. The diagnosis was made by positive herpes simplex virus culture from the throat, and was confirmed at autopsy by typical Cowdry's type A intranuclear inclusions in hepatocytes with positive herpes simplex virus culture from the liver. Review of the literature reveals that other reported cases have had very similar clinical findings, making disseminated herpes simplex infection with fulminant hepatitis a recognizable syndrome. The authors conclude based on this case report and a literature review that disseminated herpes simplex infection with fulminant hepatitis is a recognizable syndrome.

0556 HEPATITIS B ANTIGEN, AUTO-ANTIBODIES AND LIVER DISEASE IN A HAEMODIALYSIS AND TRANSPLANTATION UNIT. (Eng.) Campion, E. C.; Wangel, A. G.; Lawrence, J. R. (Queen Elizabeth Hosp., Woodville, South Australia). *Aust. N.Z. J. Med.* 5(4):314-318, 1975.

The detection of hepatitis B antigen and antibody (HBAg and HBAb) autoantibodies and the occurrence of liver disease among members of a renal hemodialysis and transplantation unit between February 1970 and December 1972 is described. During this period, 14% of 86 patients on maintenance hemodialysis, 25% of 88 renal transplant recipients, and 5% of 75 staff members were HBAg-positive. Three of 38 family members of antigen-positive patients developed hepatitis; all were either antigen- or antibody-positive. Both immunoelectroosmophoresis and radioimmunoassay were used to detect HBAg. No additional carriers were identified among the dialysis or transplant patients by applying the more sensitive technique, although two persons with hepatitis were positive only by radioimmunoassay. None of the staff members who developed antigen-positive hepatitis died, and no one became a carrier. Dialysis patients who had icteric hepatitis also cleared the antigen from the serum. Clinical hepatitis did not occur in immunosuppressed graft recipients who were carriers of the *ay* subtype of the antigen, nor was there histological evidence of liver disease in 18 of 19 of such carriers studied. Moreover, there was no association between long term presence of the antigen and the presence of the autoantibodies characteristic of chronic active hepatitis. Rapid reduction of immunosuppression was followed by acute hepatitis in one carrier, while another, whose antigen was of the *ad* subtype, developed micronodular cirrhosis.

0557 HEPATITIS B "IMMUNE" GLOBULIN: EFFECTIVENESS IN PREVENTION OF DIALYSIS-ASSOCIATED HEPATITIS. (Eng.) Prince, A. M.; Szmuness, W.; Mann, M. K.; Vyas, G. N.; Grady, G. F.; Shapiro, F. L.; Suki, W. N.; Friedman, E. A.; Stenzel, K. H. (Natl. Heart and Lung Inst., Bldg. 31, Bethesda, MD 20014). *N. Engl. J. Med.* 293(21):1063-1067; 1975.

A randomized, double-blind, multicenter study of hepatitis prevention by immune serum globulin with high antihepatitis B surface antigen, titer ("hepatitis B immune globulin") was carried out among 318 new patients and 296 staff members of renal dialysis units. High titer globulin, 3 ml, dose repeated at 4 months, was compared with equal doses of intermediate or normal titer globulin. Among staff members, the cumulative percentages developing hepatitis or hepatitis B surface antigen or both within 8 months were 6.9, 11.7, and 11.1 in the high, intermediate, and normal titer groups, resp. The lower incidence associated with high titer globulin was not significant ($p>0.05$). However, among the patients the percentages were 7.9, 21.3, and 23.1, resp., and the lower incidence in the high titer globulin group was significant ($p<0.01$). The results suggest that repeated administration of hepatitis B immune globulin will provide a useful means of reducing the incidence of hepatitis B among patients, and possibly the staff, in renal dialysis units.

0558 CLINICAL TRIALS OF HEPATITIS B IMMUNE GLOBULIN. DEVELOPMENT OF POLICIES AND MATERIALS FOR THE 1972-1975 STUDIES SPONSORED BY THE NATIONAL HEART AND LUNG INSTITUTE. (Eng.) Surgenor, D. M. N.; Chalmers, T. C.; Conrad, M. E.; Friedewald, W. T.; Grady, G. F.; Hamilton, M.; Mosley, J. W.; Prince, A. M.; Stengle, J. M. (Natl. Heart and Lung Inst., Bethesda, MD 20014). *N. Engl. J. Med.* 293(21):1060-1062; 1975.

Protocols developed by a single policy board for four interlocking clinical trials, in which a hepatitis B "immune" globulin was studied for its ability to prevent or modify hepatitis B infections, are discussed. Plasma from persons with high titers of hepatitis B antibody was used to manufacture one lot of immune globulin sufficient for the four related studies. The trials were carried out in renal dialysis units, in medical personnel with accidental exposures to hepatitis B, in transfused patients, and in patients with fulminant hepatitis. The board developed protocols that allowed comparisons among the four studies while respecting the unique requirements of each.

0559 REVIEW OF INFECTIVITY STUDIES IN NONHUMAN PRIMATES WITH VIRUS-LIKE PARTICLES ASSOCIATED WITH MS-1 HEPATITIS. (Eng.) Maynard, J. E.; Lorenz, D.; Bradley, D. W.; Feinstone, S. M.; Krushak, D. H.; Barker, L. F.; Purcell, R. H. (Phoenix Lab., 4402 North 7th St., Phoenix, AZ 85014). *Am. J. Med. Sci.* 270(1):81-85; 1975.

Hepatitis A infectivity studies were conducted in marmoset monkeys (*Saguinus mystax*) and chimpanzees by immune electron microscopy. Marmosets inoculated with human serum containing the MS-1 strain of hepatitis A virus developed viral hepatitis (9/20 in passage 1, 8/19 in passage 2, 3/7 in passage 3, and 8/8 in passage 4). In addition, 7/7 animals with hepatitis and 2/6 without illness seroconverted to 27 nm virus-like particles isolated from stools of humans in the early acute stages of hepatitis. Similar results were observed through several marmoset subpassages, and the virus-like particles were recovered from the liver of animals in the acute phase of hepatitis. Chimpanzees inoculated with stool filtrates containing the virus-like particles developed hepatitis with concomitant excretion of the particles in early acute phase stools and subsequent development of serum antibody to the particles. These results confirm the susceptibility of the *S. mystax* subspecies to infection with MS-1 hepatitis A virus and indicate the ability of this agent to maintain pathogenicity and infectivity through several animal subpassages. The authors suggest that virus-like particles of stool filtrates constitute the virus of hepatitis A of the MS-1 prototype.

0560 HEPATITIS B VIRUS INFECTION IN CHIMPANZEES: TITRATION OF SUBTYPES. (Eng.) Barker, L. F.; Maynard, J. E.; Purcell, R. H.; Hoofnagle, J. H.; Berquist, K. R.; London, W. T.; Gerety, R. J.; Krushak, D. H. (Bureau Biologics, 8800 Rockville Pike, Bethesda, MD 20014). *J. Infect. Dis.* 132(4):451-458; 1975.

Chimpanzees (34) were inoculated i.v. with sera containing the adw, ayw, adr, or ayr subtype of hepatitis B surface antigen (HB_sAg), and the serologic events and disease manifestations are presented. Infectivity titers were established for the inocula by counterimmunoelectrophoresis, complement fixation, and radioimmunoassay. Twenty-nine animals became infected with hepatitis B virus, and in every instance the subtype of HB_sAg in the infected animal was the same as the subtype in the inoculum. The patterns of serologic events varied in the infected animals but included most of the typical patterns of serologic change seen in human cases of type B hepatitis. Mild disease, manifested by elevated concentrations of serum enzymes and changes detected by liver biopsy, occurred in 23 of the 29 infected animals. There was no correlation between HB_sAg titer and infectivity titer or between virus dose and severity of disease. A direct relation between dose of inoculated virus for the three relatively high-titered subtypes (adw, ayw, and adr) and the incubation periods before appearance of HB_sAg and SGPT elevations was observed. The results demonstrate that chimpanzees are quite sensitive to HBV infection, an important asset for their evaluation of experimental vaccines and passive immunization.

0561 HEPATITIS B_S ANTIGEN, MALARIA TITERS, AND PRIMARY LIVER CANCER IN SOUTH VIETNAM. (Eng.) Welsh, J. D.; Brown, J. D.; Arnold, K.; Mathews, H. M.; Prince, A. M. (Univ. Oklahoma Health Sci. Center, Post Office Box 26901, Oklahoma City, OK 73190). *Gastroenterology* 70(3):392-396; 1976.

Possible associations between hepatitis B surface antigen (HB_sAg) or chronic malaria and primary liver cancer in South Vietnam were investigated. A total of 306 individuals from South Vietnam were studied: 61 had a diagnosis of primary liver cancer (38 had a tissue diagnosis, and 23 had a clinical diagnosis and a positive alpha-fetoprotein), 9 had viral hepatitis, 101 were hospitalized patients (60 with various other forms of liver disease and 41 without liver disease), 94 were blood donors, 29 were drug users, and 12 were normal controls. Alphafetoprotein was present in 45 of 61 (74%) of those with a diagnosis of primary liver cancer (PLC) and in none of the other patients. Using immunoelectroosmophoresis, HB_sAg was found no more frequently in those with PLC than in the other groups studied. In contrast, using a radioimmunoassay technique HB_sAg was present 3-8 times as frequently in the PLC patients as in other subjects without viral hepatitis. There was a close relationship between the presence of alpha-fetoprotein and HB_sAg in the patients with PLC. Malaria seropositivity rates were no different in the PLC groups than the other groups. It appears that in South Vietnam PLC is associated with an increased frequency of HB_sAg.

0562 LASSA VIRUS HEPATITIS. OBSERVATIONS ON A FATAL CASE FROM THE 1972 SIERRA LEONE EPIDEMIC. (Eng.) Winn, W. C., Jr.; Monath, T. P.; Murphy, F. A.; Whitfield, S. G. (Univ. Virginia Sch. Charlottesville, VA 22903). *Arch. Pathol. Pathol.* 99(11):599-604, 1975.

A case of fatal Lassa fever in a pregnant 20-yr-old woman is described. The patient developed an acute febrile disease with tonsillar exudates and hemorrhagic manifestations. Lassa virus was isolated in cell cultures from pharyngeal secretions and pleural fluid and was identified by complement fixation. Typical arenavirus particles were observed in these infected cell cultures. In a liver biopsy specimen, diffuse hepatocellular damage and focal necroses were evident, with a spectrum of liver cell change ranging from slight vacuolization to frank lysis. The virus was frequently observed in nearby extracellular spaces and was clearly associated with hepatocytes rather than sinusoidal cells. The demonstration for the first time of Lassa virus particles in human tissue provides direct evidence that the virus is responsible for the observed pathologic changes.

0563 HEPATIC DISEASE IN ASYMPTOMATIC PARENTERAL NARCOTIC DRUG ABUSERS: A VETERANS ADMINISTRATION COLLABORATIVE STUDY. (Eng.) Seef, L. B.; Zimmerman, H. J.; Wright, E. C.; Schiff, E. R.; Kiernan, T.; Leevy, C. M.; Tamburro, C. H.; Ishak, K. G. (Veterans Admin. Hosp., South Irving St., N. W., Washington, DC 20422). *Am. J. Med. Sci.* 270(1):41-47; 1975.

A collaborative study was initiated to investigate clinically asymptomatic parenteral drug addicts for evidence of liver disease at the time of entry and during an extended evaluation period. Preliminary data from 347 patients who have completed at least 3 months of follow-up evaluation revealed that on admission, abnormal serum transaminase values were demonstrated in 50%, HB_sAg in 7%, and anti-HB_s in 59%. The frequency of these findings increased during the follow-up evaluation; only 19% remained entirely free of one or more of these abnormalities. Definable hepatologic disease (acute or chronic hepatitis, alcoholic hepatitis) developed in 46%. However, among 60 of them subjected to liver biopsy, a poor correlation was noted between the clinical and histologic diagnoses. In particular, routine liver function and immunologic tests did not discriminate between histologically detected chronic active and chronic persistent hepatitis. However, HB_sAg was present significantly more frequently in those with chronic active hepatitis. Wide variability of histologic diagnoses was seen among patients subjected to more than one biopsy, apparent progression and regression of the lesion being noted. The results demonstrate the hazard of attempting to assign a prognosis to the disease on the basis of a single liver biopsy specimen, and suggest that repeated biopsies should be mandatory for the evaluation of chronic liver disease in drug addicts.

0564 STUDIES ON THE PATHOGENESIS OF CHRONIC INFLAMMATORY LIVER DISEASES: I. MEMBRANE-FIXED IgG ON ISOLATED HEPATOCYTES FROM PATIENTS. (Eng.) Hopf, U.; Arnold, W.; Meyer Zum Buschenfelde, K. H.; Forster, E.; Bolte, J. P. (Second Dept. Internal Medicine, Univ. Mainz, Mainz, West Germany). *Clin. Exp. Immunol.* 22(1):1-8; 1975.

The presence of membrane-fixed IgG on isolated hepatocytes from patients with acute and chronic inflammatory liver diseases, and its relation to the inflammatory process and/or to serological autoimmune phenomena were investigated. Studies were performed on 46 patients with acute virus A and B hepatitis (hepatitis B surface antigen [HB_sAg]-positive, 34 patients and HB_sAg-negative, 12), 49 with chronic active hepatitis (CAH) of different stages (HB_sAg-positive, 16 and -negative, 33), 13 with chronic persistent hepatitis (CPH, all negative for HB_sAg), and 14 patients with metabolic liver diseases (fatty liver, 8 patients; alcoholic cirrhosis, 4; hemochromatosis, 1; alkylphosphate intoxication, 1). In the CAH group, 32 cases (5 HB_sAg-positive and 27 HB_sAg-negative) were under immunosuppressive therapy with azathioprine and 10 mg prednisone/day when biopsies were taken. Liver tissue was obtained by percutaneous biopsy or by laparoscopy. Determination of HB_sAg and anti-HB_sAg in serum was performed by counter-immunoelectrophoresis, by complement fixation test in an autoanalyzer system, and by radioimmunoassay. The detection of human liver specific proteins (HLP) was performed by counter-immunoelectrophoresis, using monospecific heteroimmune serum from rabbits. The antibody titer against HLP was tested by a passive hemagglutination microtechnique. Membrane-fixed IgG was demonstrated on isolated hepatocytes from biopsy material by direct immunofluorescence in 9/34 patients with acute virus B hepatitis and in 17/49 cases with CAH. Patients with acute virus A hepatitis, CPH, or metabolic liver diseases did not show this phenomenon. Cases of CAH with IgG on the hepatocytes, (HB_sAg-positive as well as HB_sAg-negative) had high inflammatory activity. Antibodies against HB_sAg were not present in any serum. Autoimmune phenomena (antibodies against smooth muscle, mitochondria, and nuclei) were only rarely demonstrable. The authors conclude that an antibody- or immune complex-mediated lymphocyte toxicity may be involved in the pathogenesis of chronic liver diseases.

LIVER AND BILIARY TRACT

Chronic Hepatitis

0578 DYNAMIC STUDIES ON THE PORTAL HEMODYNAMICS BY SCINTIPHOTOSPLENOPORTOGRAPHY. STREAMLINE FLOW IN THE HUMAN PORTAL VEIN. Kashiwagi, T.; Kamada, T.; Abe, H. (Osaka Univ. Medical Sch., Osaka, Japan). *Gastroenterology* 69(6):1292-1296; 1975.

To demonstrate streamline flow in the human portal vein, the hepatic lobar distribution of splenic flow was studied in six patients without liver disease and four patients with chronic hepatitis using a new technique scintiphotosplenoportography, followed by ^{198}Au-colloid liver scintigraphy. In two patients, a $^{99m}\text{TcO}_4^-$ bolus injected into the spleen drained predominantly into the left lobe of the liver. A repeat examination in one patient revealed that the bolus was chiefly directed to the right lobe. The distribution of $^{99m}\text{TcO}_4^-$ radioactivity was the same as that observed with ^{198}Au-colloid in three patients. In the other five the predominant distribution of $^{99m}\text{TcO}_4^-$ was observed in the right lobe. In 8 of 11 studies, splenic flow was distributed either to the right or left lobe instead of diffusely to both lobes. This result suggests that flow in the human portal vein is streamline rather than turbulent.

0579 HEPATIC BLOOD FLOW WITH COLLOIDAL ^{198}Au IN THE DIAGNOSIS OF CHRONIC HEPATITIS IN CHILDREN. (Eng.) Marian, L.; Szantay, V. (First Clinic Pediatrics, Cluj, Rumania). *Nucl. Med. (Stuttg.)* 14(2):158-162; 1975.

Hepatic blood flow (HBF) was evaluated with colloidal ^{198}Au (20-25 μCi) in 25 children with chronic hepatitis (13 cases of active and 12 cases of progressive chronic hepatitis) and 15 healthy controls. In 16 cases (8 cases of active and 8 cases of progressive chronic hepatitis), hepatic scintigrams were also obtained (with colloidal ^{198}Au or ^{99m}Tc). The HBF values in the control group aged 4-10 yr, varied from 306 to 520 ml/min (mean value of 421 ± 93.8 ml/min). In controls aged 12-15 yr, the HBF values were between 704 and 1177 ml/min (mean value of 841 ± 172.8 ml/min). The mean HBF value was 298 ± 78 ml/min and 604 ± 44.2 ml/min in children with chronic active hepatitis aged 4-10 yr and 12-15 yr, resp. The mean HBF value was 199 ± 37 ml/min and 426 ± 112 ml/min in children with progressive chronic hepatitis aged 4-10 yr and 12-15 yr, resp. HBF values were significantly lower in patients with progressive chronic hepatitis than in those with active chronic hepatitis. However, HBV values in all patients were significantly lower than in the controls, suggesting the existence of intrahepatic circulatory disturbances in both active and progressive chronic hepatitis. Scintigrams in active chronic hepatitis were pathological in only 25% of the cases. The authors conclude that the determination of the HBF is valuable for the diagnosis of active nonprogressive forms of chronic hepatitis in which the scintigram is normal, the clinical signs are less characteristic, and the results of biochemical functional tests and of the histological examination of the liver are inconclusive.

0580 ABNORMALITIES OF CHEMICAL TESTS FOR COPPER METABOLISM IN CHRONIC ACTIVE LIVER DISEASE: DIFFERENTIATION FROM WILSON'S DISEASE. (Eng.) LaRusso, N. F.; Summerskill, W. H. J.; McCall, J. T. (Mayo Clinic, Foundation and Medical Sch., Rochester, MN 55901). *Gastroenterology* 70(5):653-655; 1976.

Hepatic copper concentration, 24-hr urinary copper excretion, and serum ceruloplasmin concentration were measured in 54 patients with chronic active liver disease (CALD), and the abnormal findings were compared with those that characterize Wilson's disease (WD). Twenty-four hour urinary copper excretion was increased in about 50% of the patients, was significantly higher during active disease compared to remission, and was in the WD range in approximately 10% of patients. Hepatic copper concentration was also increased in the majority of patients, generally during active disease, and it sometimes overlapped with values reported in WD. By contrast, serum ceruloplasmin levels were elevated in nearly half the CALD patients and were never below normal. The authors conclude that the chemical tests routinely used to assess copper metabolism in WD are frequently abnormal in CALD. It is suggested that because serum ceruloplasmin concentrations never fall in the WD range and are often elevated, it is the most reliable routine chemical screening test to differentiate between CALD and WD.

0581 ORCEIN POSITIVE HEPATOCELLULAR MATERIAL IN HISTOLOGICAL DIAGNOSIS OF PRIMARY BILIARY CIRRHOSIS. (Eng.) Sipponen, P.; Salaspuro, M. P.; Makkonen, H. M. (Central Lab. Pathology, Haartmaninkatu 3, 00290 Helsinki 29, Finland). *Ann. Clin. Res.* 7(4):273-277; 1975.

The value of the orcein staining method in the histological diagnosis of primary biliary cirrhosis (PBC) was studied by comparing the orcein staining in liver specimens of patients with clinically, biochemically, and immunologically typical PBC with those of patients with chronic active hepatitis (CAH). Liver biopsies from 18 patients with PBC and from 25 patients with CAH were stained by orcein after oxidation of the tissue sections with potassium permanganate. In 15 out of the 18 PBC cases, the hepatocytes, usually periportally, contained cytoplasmic stainable material. Five CAH patients contained the same material, but four of these patients were clinically atypical and showed features of the cholestatic form of CAH and features crosslinking with PBC. All patients in both groups were serologically hepatitis-B antigen negative. Orcein staining seems to be a reliable addition to histological differentiation between PBC and CAH.

0582 TRIGGER FACTORS AND HL-A ANTIGENS IN CHRONIC ACTIVE HEPATITIS. (Eng.) Lindberg, J.; Lindholm, A.; Lundin, P.; Iwarson, S. (Blood Center, Sahlgrenska Sjukhuset, Gothenburg, Sweden). *Br. Med. J.* 4(5988):77-79; 1975.

Patients (46) with chronic active hepatitis (CAH) were classified according to possible trigger factors, and the distribution of HL-A antigens and the trigger factors were correlated. HL-A antigens were determined by the lymphocytotoxicity microtechnique. The patients with histologically verified CAH were divided into three groups according to whether the CAH was virus-induced (15 cases), drug-induced (13 cases), or cryptogenic. The frequency of the HL-A antigens 1 and 8 was increased in the 18 patients with cryptogenic hepatitis, while the other groups did not differ significantly from healthy controls. Autoantibodies were often found in high titers in the drug-induced and cryptogenic groups but were infrequent in the virus-induced group. Although the results support the hypothesis that patients with HL-A types 1 and 8 are prone to develop CAH, they do not exclude the possibility that these patients develop CAH due to an impaired suppressor T-cell function.

0583 ARTHRITIS ASSOCIATED WITH CHRONIC ACTIVE HEPATITIS: COMPLEMENT ACTIVATION AND CHARACTERIZATION OF CIRCULATING IMMUNE COMPLEXES. (Eng.) Wands, J. R.; Alpert, E.; Isselbacher, K. J. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 69(6):1286-1291; 1975.

Ten patients with chronic active hepatitis (CAH) were studied in an attempt to isolate, purify, and characterize ciruclating cryoprotein immune complexes. Circulating immune complexes were identified in cryoproteins isolated from serial serum samples from six CAH patients with frank arthritis or arthralgias. These immune complexes were not detectable in patients with uncomplicated CAH. Only cryoprecipitates from CAH patients with frank arthritis contained IgG, IgM, IgA (demonstrated by double diffusion in agar gel), and complement components C_3, C_4, and C_5 (assayed by counterimmunoelectrophoresis). These circulating immune complexes disappeared with resolution of arthritis. Hepatitis B surface antigen was concentrated severalfold in the cryoprotein immune complexes as compared with the serum concentration. The C_3 activator fragment of the properdin complex was found in fresh serum of all patients with arthritis but was undetectable in patients with arthralgias and uncomplicated CAH. The authors conclude that the presence of circulating complement-fixing immune complexes in patients with CAH and arthritis is associated with activation of both classical and alternate complement pathways, and suggests that they play an important role in the pathogenesis of the arthritis.

0584 HAEMOCHROMATOSIS, ACTIVE CHRONIC HEPATITIS, AND FAMILIAL IgA DEFICIENCY. (Eng.) Joske, R. A.; Traub, M. (Dept. Medicine, University of Western Australia, Perth, Australia). *Digestion* 12(1):32-38; 1975.

A case report was presented to compare the relation between hemochromatosis, active chronic hepatitis (ACH), and familial IgA deficiency. A 38-yr-old man presented with a weight loss of 13 kg over a 1-yr period that was accompanied by muscular wasting and increased skin pigmentation. The liver was enlarged 10 cm below the costal margin and the spleen was palpable. Laboratory studies and liver biopsy confirmed hemochromatosis with chemical diabetes mellitus and hepatic cirrhosis. Increases in serum bilirubin, alkaline phosphatase, and SGOT were noted. Autoantibodies (IgG) were consistently present in the serum and the antinuclear reaction was homogeneous and nucleolar. Lupus erythematosus cells were abundant. Familial studies revealed the absence of liver disease or hemochromatosis in all members and the absence of IgA in the patient's brother and niece. Venesection and 51 phlebotomies were ineffective as treatment. Prednisone (p.o., 15 mg daily) produced symptomatic relief and improvement in the biochemical abnormalities of hepatic and renal function. This case provides evidence that hemochromatosis may initiate ACH in genetically susceptible subjects.

0585 THE USE OF FRESH FROZEN PLASMA OR A CONCENTRATE OF FACTOR IX AS REPLACEMENT THERAPY BEFORE LIVER BIOPSY. (Eng.) Gazzard, B. G.; Henderson, J. M.; Williams, R. (King's Coll. Hosp. and Medical Sch., London, England). *Gut* 16(8):621-625; 1975.

The use of fresh frozen plasma or a concentrate of factor IX for the correction of a coagulation defect in 30 patients with various types of chronic liver disease and a prothrombin time prolonged for ≥ 4 sec who required needle liver biopsy were compared. Patients were given either 600 ml of fresh frozen plasma, i.v., over a 0.5-hr period followed by 300 ml 6 hr later (15 patients) or a low i.v. injection of 20 ml concentrate of clotting factors (15 patients). The prothrombin time returned to within normal limits in 7/15 patients given the concentrate and in 3 of those receiving fresh frozen plasma. Levels of factors II, IX, and X increased about 30% following concentrate administration; corresponding rises in the group given fresh frozen plasma were less due to the smaller quantity of clotting factors administered with fresh frozen plasma. The increase in factor II and IX activity/kg body weight/U of clotting factor injected was greater when fresh frozen plasma was used. In neither group was there clinical evidence of bleeding, but most of the clotting factor levels, except in factor II, before biopsy were above those normally required for hemostasis. No evidence of disseminated intravascular coagulation was found with the concentrate injection, but HBAg appeared some months later in three patients, two from the concentrate group and one from those given fresh frozen plasma. However, the conversion of these patients to HBAg positive may be unrelated to the clotting factor replacement therapy. The results demonstrate partial correction of the coagulation defect in both groups of patients without any immediate side effects attributable to these prophylactic measures. The advantage of a concentrate over fresh frozen plasma for replacement therapy is that larger quantities of clotting factors can be administered in a small volume of fluid.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

0596 T ROSETTES IN ALCOHOLIC CIRRHOSIS OF THE LIVER. (Eng.) Berenyi, M. R.; Straus, B.; Avila, L. (Beth Israel Medical Center, 10 Nathan D. Perlman Pl., New York, NY 10003). *JAMA* 232(1): 44-46; 1975.

In vivo and *in vitro* correlates of cell-mediated immunity were studied in 30 patients with alcoholic liver disease and 10 healthy controls. The *in vivo* assessment of cellular immunity was performed with four dermal antigens. Among the 30 patients, the incidence of negativity to an intermediate-strength purified protein derivative was 53%; to streptokinase-streptodornase, 30%; and to *Candida albicans*, 50%. However, 77% failed to be sensitized to dinitrochlorobenzene, indicating impairment of the *in vivo* cellular response. Determination of active or spontaneous T-rosette formation with uncoated sheep RBC involved a short centrifugation and incubation time for the lymphocytes and sheep RBC. This procedure identified only that subpopulation of T-cells with a high affinity for sheep RBC. In 16 patients, blastogenesis, as measured by ^{14}C-labeled thymidine incorporation, was normal in all cases when phytohemagglutinin was added to the cell culture. In 26 patients with alcoholic liver disease, the mean number of rosette-forming cells in the peripheral blood (27.4%) was significantly less than the number in controls (36.2%). This finding suggests that the active T-rosette test is a valuable tool in determining partial alterations in cell-mediated immunity in alcoholic liver cirrhosis. Further, the authors suggest that rosette formation is a more sensitive indicator of cell-mediated immunity than phytohemagglutinin-stimulated blastogenesis in these patients.

0597 LOCALIZATION OF T AND B CELLS AND ALPHA FETOPROTEIN IN HEPATIC BIOPSIES FROM PATIENTS WITH LIVER DISEASE.

(Eng.) Husby, G.; Strickland, R. G.; Caldwell, J. L.; Williams, R. C., Jr. (Univ. New Mexico Sch. Medicine, Albuquerque, NM 87131). *J. Clin. Invest.* 56(5):1198-1209; 1975.

Peripheral blood and hepatic tissue T- and B-lymphocyte distributions, serum alpha fetoprotein (AFP) concentrations, and hepatic AFP were studied in 46 patients undergoing diagnostic percutaneous liver biopsy (26 with alcoholic liver disease, 13 with nonalcoholic hepatitis or cirrhosis, and 7 with either normal hepatic histology or minor nonspecific changes). Serum AFP was determined by radioimmunoassay and hepatic tissue AFP by indirect immunofluorescence. Peripheral blood T lymphocytes were identified by the sheep red-cell rosette technique and B lymphocytes by fluoresceinated anti-immunoglobulin antisera and immunoglobulin G (IgG) aggregates. Tissue identification of T lymphocytes was accomplished using an extensively absorbed rabbit antihuman thymocyte antiserum and indirect immunofluorescence; tissue B lymphocytes were identified using pepsin F (ab')2 fragments of rabbit IgG antibodies to human immunoglobulins. T lymphocytes predominated in hepatic lymphoid infiltrates from patients with alcoholic liver disease (91%), whereas in patients with chronic active or chronic persistent hepatitis, viral hepatitis, or cryptogenic cirrhosis, proportions of T and B lymphocytic infiltrates were similar. Hepatic tissue AFP was detected in 9 of 18 patients with alcoholic hepatitis; serum AFP was increased in only 1 of these 9. Tissue AFP was not observed in the remaining biopsy material nor were serum AFP concentrations increased. Peripheral blood T-cell numbers were significantly decreased in patients with alcoholic liver disease and in nonalcoholic hepatitis or cirrhosis. The results demonstrate a close relation between peripheral blood T-lymphocytopenia and hepatic T-cell infiltrates in patients with alcoholic liver disease; this relation is less apparent in patients with nonalcoholic hepatitis or cirrhosis.

0598 ISOLATION AND ELECTROPHORETIC STUDY ON MALLORY BODIES FROM THE LIVERS OF ALCOHOLIC CIRRHOSIS.

(Eng.) Okamura, K.; Harwood, T. R.; Yokoo, H. (Northwestern Univ. Medical Sch., Chicago, IL 60611). *Lab. Invest.* 33(2):193-199; 1975.

The isolation procedures and the results of an electrophoretic study on Mallory bodies (MB) obtained from the livers of eight subjects with alcoholic cirrhosis were described. Liver slices were homogenized with an ice-cold isolation medium (0.25 M sucrose buffered to pH 8.5), subjected to velocity sedimentation in 60% sucrose solution, and centrifuged using a two-phase polymer system with polyethylene glycol-dextran. MB were isolated in large quantity and high purity (more than 95% in some cases) and they maintained characteristic filamentous structures. Isolated MB were solubilized in 6 M guanidine hydrochloride in 10% or 1% acetic acid by sonication or in 1% sodium dodecyl sulfate with 5% 2-mercaptoethanol and 8 M urea. The solubilized MB protein produced three peaks on Sephadex G-100 chromatography and at least five intense protein bands on sodium dodecyl sulfate polyacrylamide gel electrophoresis. The fractions from control livers contained several bands that were identical with the major components of isolated MB protein. These findings suggest that MB are not homogeneous protein, but are probably complexes of various proteins, and that some components of MB are present in normal hepatocytes.

0599 ETHANOL AND GALACTOSE METABOLISM AS INFLUENCED BY 4-METHYLPYRAZOLE IN ALCOHOLICS WITH AND WITHOUT NUTRITIONAL DEFICIENCIES: PRELIMINARY REPORT OF A NEW APPROACH TO PATHOGENESIS AND TREATMENT IN ALCOHOLIC LIVER DISEASE.

(Eng.) Salaspuro, M. P.; Lindros, K. O.; Pikkarainen, P. (Second Dept. Medicine, Univ. Helsinki, Haartmaninkatu 4, 00290 Helsinki 29, Finland). *Ann. Clin. Res.* 7(4):269-272; 1975.

The ethanol elimination rate, the influence of ethanol on the galactose elimination rate, and the effect of 4-methylpyrazole (4-MP) were determined in two normal volunteers, in two alcoholics with inadequate food consumption, and in two alcoholics with adequate food consumption. 4-MP reduced ethanol elimination by 30-50% and completely removed the ethanol-induced inhibition of galactose elimination in the control subjects. Ethanol elimination was accelerated in the alcoholics with adequate nutrition, but the effect of 4-MP was comparable to that in controls. In the alcoholic subjects who reported poor nutritional intake, intermediate rates of ethanol elimination were observed, and 4-MP had almost no effect on ethanol or galactose elimination. These results suggest that alcohol abuse may result in an increased contribution to ethanol elimination by pathways other than that involving alcohol dehydro-

LIBRARY U. OF I. URBANA-CHAMPAIGN

genase (ADH) and that the decreased contribution from ADH, possibly potentiated by inadequate nutrition, may diminish the ethanol-induced shift in the NAD-coupled redox state. Since liver damage produced by alcohol abuse is believed to be related to changes from the normal redox state caused by ethanol, these results may explain why alcoholic liver damage is uncommon in alcoholics living on a marginal diet. Since 4-MP effectively eliminates the ethanol-induced shift in the redox state, a therapeutic trial with 4-MP in alcoholics with a high risk for liver disease is indicated.

0600 ANIMAL MODELS OF ETHANOL DEPENDENCE AND LIVER INJURY IN RATS AND BABOONS. (Eng.) Lieber, C. S.; Decarli, L. M. (Veterans Admin. Hosp., Bronx, NY 10468). *Fed. Proc.* 35(5):1232-1236; 1976.

A model for the study of ethanol-related injury in which ethanol is administered to Sprague-Dawley rats and baboons as part of a nutritionally adequate liquid diet is described. The rat diet included casein and dextrin-maltose, and 18% of the total calories as protein, 35% as fat, 11% as carbohydrate, and 36% as ethanol. The baboon liquid diet also included casein and dextrin-maltose, and 18% of the total calories as protein, as much as 50% as ethanol, and 11% as carbohydrate. With this regimen, ethanol intake was much higher than with conventional procedures. All animals gained or maintained their body weight, and liver morphology was normal in the controls. Isocaloric substitution of carbohydrate by ethanol (36% of total calories in rats and 50% in baboons) resulted in the production of fatty liver in all animals, while the baboons also developed alcoholic hepatitis and cirrhosis with increased activities of SGOT. Inebriation and manifestation of dependence on withdrawal of the diet were observed in baboons and quantitated in the rat. Chemical alterations produced by ethanol at the fatty liver stage were characterized by hyperlipemia, striking triglyceride accumulation in the liver, and enhanced activities of microsomal drug metabolizing enzymes, including the microsomal ethanol oxidizing system. The demonstration that all aspects of liver injury observed in alcoholics can be reproduced in animals by the feeding of pure ethanol with an adequate diet, indicates that ethanol itself is a cause for hepatic complications. This new model is proposed as a tool for the study of the pathogenesis and treatment of alcoholic liver injury and dependence.

LIVER AND BILIARY TRACT

Cirrhosis

0607 MORPHOLOGICAL FEATURES AND PROBABLE MODE OF EVOLUTION OF CIRRHOSIS OF THE LIVER IN ADULTS IN NORTH INDIA. (Eng.) Aikat, B. K.; Ghosh, R. N.; Chhuttani, P. N.; Dutta, D. V. (Post-graduate Inst. Medical Education and Res., Chandigarh, India). *Indian J. Med. Res.* 63(12):1747-1760; 1975.

A total of 250 cases of cirrhosis, 92 from autopsy and 158 from biopsy material, were analyzed to determine the prevalence of different morphological types in North India and to determine the possible roles of alcohol, viral hepatitis, and malnutrition in its etiopathogenesis. They were classified into macronodular (60.4%), micronodular (15.6%), mixed (11.2%), and unclassified end-stage diseases (3.2%). Atrophy of the left lobe was observed in 35.3% of macronodular cirrhosis and was not observed in the micronodular type. Fatty change was observed in the majority of the micronodular cirrhosis (69.3%) and among alcoholics (80%). However, fatty metamorphosis was also present in other types of cirrhosis. Mallory's hyaline was observed most frequently in the alcoholics, but was also observed in nonalcoholic cirrhosis. A combination of steatosis, steatonecrosis, and Mallory's hyaline along with satellitosis was considered morphological evidence of alcoholic cirrhosis with alcoholic hepatitis. Chronic alcoholism was responsible for 25.2% of all cirrhoses. Significant past history of jaundice was observed in 20.4%. Chronic aggressive hepatitis as a sequel of viral hepatitis was observed in 25.9% hepatitis cases during the same period. There was no evidence to suggest any cause and effect relationship between protein calorie malnutrition and cirrhosis of the liver.

0608 DISTRIBUTION OF SERUM ZINC BETWEEN ALBUMIN AND α_2-MACROGLOBULIN IN PATIENTS WITH DECOMPENSATED HEPATIC CIRRHOSIS.

(Eng.) Schechter, P. J.; Giroux, E. L.; Schlienger, J. L.; Hoenig, V.; Sjoerdsma, A. (Centre de Recherche Merrell International, 16, rue d'Ankara, F-67000 Strasbourg, France). *Eur. J. Clin. Invest.* 6(2):147-150; 1976.

Zinc distribution in the serum of patients with decompensated alcoholic cirrhosis was studied by an improved fractionation technique for albumin-bound and α_2-macroglobulin-bound zinc. Lower concentrations of total serum zinc (540 ± 111 µg/l), and of albumin-bound serum zinc (295 ± 113 µg/l) and a higher concentration of α_2-macroglobulin-bound zinc (245 ± 69 µg/l) were found in 25 patients with decompensated hepatic cirrhosis, compared to 28 healthy subjects (835 ± 91; 679 ± 83; 156 ± 27 µg/l, resp.). Levels of total and albumin-bound zinc were significantly and positively correlated with serum albumin levels. Higher levels of α_2-macroglobulin-bound zinc were associated with higher levels of α_2-macroglobulin in these patients (2.8 ± 0.8 g/l) compared to normals (2.3 ± 0.6). Hence, not only do decompensated cirrhotics exhibit a lower serum zinc level, but a greater proportion of this zinc is associated with the tightly bound, and presumably metabolically more inert, serum fraction. This situation exaggerates the zinc deficiency state of the severe cirrhotic.

0609 STUDIES OF THE PLASMA KININ-FORMING SYSTEM IN CIRRHOSIS OF THE LIVER.

(Eng.) Lukjan, H.; Czokalo, M.; Kiersnowska, B.; Bielawiec, M. (Medical Sch., Bialystok, Poland). *Acta Hepatogastroenterol.* 22(2):89-92; 1975.

Kininogen levels and kinin and kininase activities were studied in the plasma of 15 patients (4 women and 11 men aged 29-67 yr) with cirrhosis of the liver and in 21 healthy controls (14 women and 7 men aged 25-45 yr). The kininogen content was determined by the trypsin and acetone techniques and by means of the plasma and glandular kallikrein preparation. An increase in kininase activity and a lowered kininogen level were found in the patients. The maximal decrease in the kininogen level, determined by means of the plasma kallikreins, was substantiated in connection with the increased fibrinolytic activity of the plasma of the patients with hepatic cirrhosis.

0610 THE FORMATION OF BILE ACIDS IN PATIENTS WITH PORTAL LIVER CIRRHOSIS.

(Eng.) Einarsson, K.; Hellstrom, K.; Schersten, T. (Dept. Medicine, Serafimerlasarettet, Stockholm, Sweden). *Scand. J. Gastroenterol.* 10(3):299-304; 1975.

Bile acid kinetics were characterized in eight patients with portal liver cirrhosis using 24-^{14}C-cholic acid and randomly ^{3}H-labeled chenodeoxycholic acid. Although not significant on a statistical basis, the pool size, synthesis, and fractional turnover of cholic acid in the cirrhotic patients was smaller than in normolipidemic controls without evidence of liver disease. The most significant findings were the subnormal cholic acid: chenodeoxycholic acid ratio of both bile acid pool size and synthesis and the low concentrations of deoxycholic acid in duodenal bile specimens.

0611 ESTROGEN METABOLISM IN HYPERTHYROIDISM AND IN CIRRHOSIS OF THE LIVER.

(Eng.) Olivo, J.; Gordon, G. G.; Raffi, F.; Southren, A. L. (New York Medical Coll., 1249 Fifth Ave., New York, NY 10029). *Steroids* 26(1):47-56; 1975.

Estrogen metabolism was studied in spontaneous hyperthyroidism (Graves disease) and in alcoholic cirrhosis of the liver. The study employed three normal men and one woman as controls, four men and five women with hyperthyroidism, and seven men with cirrhosis. 6,7-^{3}H-estradiol-17β was infused (10 mCi primary dose followed by a constant infusion of 20 mCi) and plasma specimens were collected 135, 150, and 165 min after the primary dose. Estrone (E_1) and estradiol-17β (E_2) were separated by Sephadex LH 20 chromatography. The plasma concentration of E_2 was increased in men with hyperthyroidism. Although the metabolic clearance rate of E_2 was reduced, the production rate was increased above normal. In women with hyperthyroidism, the metabolic clearance rate of E_2 was also decreased, while the plasma clearance and production rates were similar to those of normal subjects. The conversion ratio of E_2 was increased in both hyperthyroid men and women. The plasma clearance of E_2 was significantly increased in men with cirrhosis; the metabolic clearance rate was normal and resulted in an increase in the production rate of E_2. The plasma concentration of E_1 was elevated in men with either disorder. The results demonstrate elevated plasma levels of E_1 and E_2 in hyperthyroidism and cirrhosis resulting from an overproduction of the estrogen. The diverse effects of hyperthyroidism and cirrhosis on estrogen metabolism may be related to differences in either the absolute level of binding protein or to the intrinsic disease process.

0612 SHUNT OPERATIONS FOR PORTAL HYPERTENSION. (Eng.) Hermann, R. E. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Surg. Clin. North Am.* 55(5):1073-1087; 1975.

A variety of portal systemic shunts for decompression of portal hypertension are described and compared: end-to-end (EE) portacaval shunt, side-to-side (SS) portacaval shunt, splenorenal (SR) shunt, the mesenteric-caval (MC) shunt, and the selective distal splenorenal (DSR) shunt. Patients must be carefully selected for shunt operations; in unselected patients with poor liver function, the mortality rate could be excessively high (50%). The ideal patient for a portal systemic shunt is under 60 yr of age with good liver function, macronodular cirrhosis, and a large portal, superior mesenteric, or splenic vein. The shunt can be performed in 2-4 hr, provides excellent decompression of portal hypertension, has a low incidence of thrombosis, and protects against recurrent hemorrhage from varices. However, it is associated with a high incidence of postshunt encephalopathy (24%). The SS portacaval shunt is more difficult to perform than the ES, requiring greater mobilization of the inferior vena cava and portal vein. The principal advantage of this shunt is that it decompresses the portal vein leading from the liver, providing outflow of portal blood away from the liver. It is the preferred shunt for patients with intractable ascites and in patients in whom reversal of flow in the portal venous system has been demonstrated. The SR portacaval shunt has a high incidence of shunt thrombosis and rebleeding from varices (20-25% of patients); however, there is a low incidence of postshunt encephalopathy. The MC shunt, "H" type, is effective in decompressing portal hypertension and may be used for patients with intractable ascites. Its disadvantages are similar to those of SS portacaval shunts. The DSR shunt leaves the superior mesenteric flow intact to the liver, and selectively decompresses the esophageal and gastric varices through the short gastric vessel, the intact spleen, and the distal splenic vein into the left renal vein. A low incidence of encephalopathy results from this procedure, but the surgery is difficult and may result in an extremely high incidence of postshunt thrombosis. This shunt cannot be used in patients with ascites. At the present time, no one shunt has proven superior in decompressing portal hypertension.

0613 BUMETANIDE IN THE TREATMENT OF HEPATIC ASCITES. (Eng.) Ring-Larsen, H. (Rigshospitalet, Univ. Hosp., Copenhagen, 2100, Denmark). *Postgrad. Med. J.* 51(Suppl. 6):77-81; 1975.

The effectiveness of bumetanide in the treatment of liver cirrhosis was determined in a short-term study, and its effects on electrolyte status and its possible toxicity were examined in a long-term study. Bumetanide was administered p.o. to 10 patients with hepatic cirrhosis and ascites. A striking diuresis and natriuresis was produced by doses of 1-6 mg daily. Potassium supplementation ($\leq$ 60 mEq daily) was required to prevent potassium depletion but otherwise there were only minor changes in serum electrolytes. There was no adverse effect on liver function. Apart from the development of Stevens-Johnson dermatitis in one patient, there were no adverse reactions to bumetanide in the treatment of liver cirrhosis.

0614 THE RECTAL ADMINISTRATION OF LACTULOSE. (Eng.) Ratnaike, R. N.; Hicks, E. P.; Hislop, I. G. (Queen Elizabeth Hosp., Woodville, South Australia 5011). *Aust. N.Z. J. Med.* 5(26): 137-140; 1975.

The effects of rectally administered lactulose upon venous ammonia levels and the electroencephalograph were studied. A lactulose colonic washout (pH 4.5) was administered to six men with portal systemic encephalopathy. Estimation of blood ammonia levels and electroencephalography were performed before and after each treatment. Five patients recorded a significant fall in blood ammonia level as a result of lactulose therapy. In the sixth subject, an enema with buffered physiological saline, pH 4.5, induced a fall in ammonia, which was not increased by subsequent lactulose solution. Improvement in the electroencephalogram was recorded in all periods where a lactulose colonic washout produced a fall in blood ammonia level. The results support the hypothesis that pH may influence intracolonic ammonia metabolism.

0615 UPPER GASTROINTESTINAL BLEEDING IN CIRRHOSIS: CLINICAL AND ENDOSCOPIC CORRELATIONS. (Eng.) Teres, J.; Bordas, J. M.; Bru, C.; Diaz, F.; Bruguera, M.; Rodes, J. (Hospital Clinico y Provincial, Univ. Barcelona, Barcelona, Spain). *Gut* 17(1):37-40; 1976.

The authors examined the clinical data of 180 episodes of upper gastrointestinal bleeding in 168 patients with cirrhosis of the liver. The source of bleeding was determined by early endoscopy in all cases. In men under the age of 50 yr and without symptoms of liver failure, bleeding was due to ruptured gastroesophageal varices in 84% of cases. Severe liver failure was associated with acute lesions of gastric mucosa in many cases. No presumptive diagnosis of the source of hemorrhage could be based on the examination of other clinical data (presence of ascites, mode of presentation and pattern of bleeding, history of ulcer disease, alcoholism, and previous medication). The results indicate that clinical data are not reliable in localizing the source of bleeding in upper gastrointestinal hemorrhage.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

0627 CHOLESCINTIGRAPHY WITH ^{99m}Tc-PENICILLAMINE. (Eng.) Krishnamurthy, G. T.; Tubis, M.; Blahd, W. H.; Endow, J. S. (VA Wadsworth Hosp. Center, Los Angeles, CA 90073). *Radiology* 115(1): 201-204; 1975.

After demonstrating the kinetics of ^{99m}Tc-penicillamine (Tc-Pen) in 7 normal female dogs and establishing the safety of the anticipated human dose in 3 other species of animals, 16 patients with suspected gallbladder disease were studied. The results were correlated with oral cholecystography and levels of serum bilirubin, alkaline phosphatase, SGOT, and SGPT. Satisfactory images of the gallbladder were obtained using a scintillation camera fitted with a pinhole collimator. The results of cholescintigraphy and contrast cholecystography compared favorably. The authors suggest that Tc-Pen is taken up by the hepatocytes and excreted into the bile canaliculi that enter the gallbladder. Tc-Pen may prove to be an ideal agent for evaluation of hepatocellular function.

0628 THE VALUE OF THE FATTY MEAL IN ORAL CHOLECYSTOGRAPHY.

(Eng.) Harvey, I. C.; Thwe, M.; Low-Beer, T. S. (Royal County Isle of Wight Hosp., Ryde, U.K.). *Clin. Radiol.* 27(1):117-121; 1976.

The authors reviewed 232 oral cholecystograms to determine the value of the fatty meal in oral cholecystography. Gallbladder opacification, duct visualization, separation of gallbladder from overlying bowel gas shadows, and the demonstration of abnormalities were assessed from prefatty meal films and then again in conjunction with those taken after fat, when contraction was also assessed. Of the 200 patients given the fatty meal, 132 were judged normal, 63 had gallstones, 4 had adenomyomatosis (1 with stones), and 2 had cholesterolosis. The postfatty meal films were found to be essential for the diagnosis of adenomyomatosis and cholesterolosis and considered to be occasionally helpful in diagnosing small stones. They were of little value in assessing the biliary ducts or separating the gallbladder from overlying bowel gas, and they were of no value in the diagnosis of functional biliary tract disorders.

0629 CLINICAL RELEVANCE OF ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP).

(Eng.) Seifert, E.; Fromm, H.; Huchzermeyer, H.; Lesch, P.; Misaki, F.; Rasmussen, C. W.; St. Stender, H. (Med. Sch. Hannover, W. Germany). *Endoscopy* 7(3): 133-138; 1975.

The clinical value of endoscopic retrograde cholangio-pancreatography (ERCP) was evaluated in 640 examinations. The frequency of questions yielded by the patients' history, biochemical examination, and standard x-ray findings were answered in 84.4%. Concerning the clinical question of both duct systems a positive answer was possible in 57.8%, of the pancreatic duct in 94.2%, and of the biliary system in 84.7%. The accuracy of visualization of the duct system increased with the experience of the examiner. In many cases the visualization of one of the two ducts was sufficient for a precise diagnosis. In 51.4% of the cases pathological lesions were found. It is concluded that ERCP is a very suitable method to establish an exact diagnosis, and that the accuracy rate to answer clinical questions is higher than expected.

0630 THE DIAGNOSIS OF CHOLESTASIS: LIPOPROTEIN X (LP-X).

(Ger.) Fischer, M.; Falkensammer, Ch.; Barouch, G.; Wuketich, St.; Kronberger, O.; Schnack, H. (Krankenhaus der Stadt Wien-Lainz, Wolkersbergenstrasse 1, A-1130 Wien, Austria). *Wien. Klin. Wochenschr.* 87(16):524-531, 1975.

The diagnostic specificity of a new method to detect obstructive jaundice by determination of lipoprotein X (LP-X) was tested in 144 patients with different types of hepatic diseases and compared with the usual chemical obstructive jaundice specific tests, such as bilirubin, SGOT, SGPT, alkaline phosphatase, leucine aminopeptidase, and γ-glutamyltranspeptidase. The LP-X test was performed using the test kit "LP-X Rapidophor" low-voltage electrophoresis of Immuno AG/Wien. The results were correlated with the histological classification of the liver biopsy specimen. In 82% of the histologically verified cases of obstructive jaundice, the result of the LP-X test was positive, while in 98.5% of the histologically negative cases, the result of the LP-X test was negative. The authors conclude that the LP-X method proved superior to chemical methods in providing a clear-cut positive or negative answer to the presence of cholestasis. In addition, the LP-X test was suitable for long-term follow-up investigation of patients with obstructive jaundice.

0631 FORMATION OF LIPOPROTEIN-X: ITS RELATIONSHIP TO BILE COMPOUNDS.

(Eng.) Manzato, E.; Fellin, R.; Baggio, G.; Walch, S.; Neubeck, W.; Seidel, D. (Div. Gerontology, Metabolic Disease, Policlinico, I-35100 Padua, Italy). *J. Clin. Invest.* 57(5):1248-1260; 1976.

The source of lipoprotein X (LP-X), its metabolism, and its fluctuations during cholestatic liver disease were studied. The lipid composition of bile LP was almost identical to LP-X; however, it differed from LP-X in its protein/lipid ratio and immunological and electrophoretic characteristics. Bile lipoprotein was converted into "LP-X-like" material *in vitro* by adding albumin or serum to native bile. The LP-X-like material formed *in vitro* was found to have physicochemical and chemical characteristics similar or identical to LP-X isolated from serum. As bile lipoprotein was converted into LP-X-like material by the addition of albumin to bile, LP-X was converted into bile-LP-like particles by adding bile salts to a LP-X-positive serum. Furthermore, experimental connection of the common bile duct to the vena cava was followed after a few hours by the appearance of LP-X-like material in the plasma. The results strongly suggest that bile LP is a precursor lipoprotein for LP-X and that it refluxes into the plasma pool under cholestatic conditions.

0632 EFFECTS OF OBESITY AND CALORIC INTAKE ON BILIARY LIPID METABOLISM IN MAN.

(Eng.) Bennion, L. J.; Grundy, S. M. (Natl. Inst. Arthritis, Metabolism, Digestive Diseases, Phoenix, AZ 85016). *J. Clin. Invest.* 56(4):996-1011; 1975.

The effects of obesity and caloric intake on biliary lipid metabolism were investigated in a series of related studies. The degree of saturation of gallbladder bile with cholesterol was significantly higher in a group of 23 obese healthy subjects than in 23 nonobese controls matched for age, sex, and race. Bile was also significantly more saturated in 11 obese subjects before than after weight reduction. The hepatic outputs of cholesterol, bile acids, and phospholipids were measured during constant duodenal infusion of formula in the same 11 subjects before and after weight reduction. Weight reduction resulted in significant reduction of cholesterol output but not of bile acid or phospholipid output. Very obese subjects had cholesterol secretion rates markedly higher than less obese subjects previously studied. In obese subjects, bile was supersaturated with cholesterol despite increased bile acid pool sizes and increased secretion rates of bile acids and phospholipids. Supersaturated bile in the obese could therefore be attributed to a single defect in lipid secretion, i.e., an excessive output of cholesterol. Nine obese men were studied on a weight maintenance diet and then during weight reduction on a 1,000-cal diet. Compared to weight maintenance, chronic caloric restriction resulted in reduced outputs of cholesterol, bile acids, and phospholipids, reduced bile acid pool size, and reduced synthesis and fecal excretion of cholesterol. Saturation of bile with cholesterol did not decrease during weight reduction, evidently because of the mobilization of cholesterol from adipose stores and the marked reduction in bile acid and phospholipid output during chronic caloric restriction. Acute alterations in caloric infusion rates did not fully reproduce the effects of chronic administration of high and low calorie diets. Likewise, chronic intake of hypercaloric diets by nonobese subjects did not reproduce the cholesterol hypersecretion characteristic of the obese. Thus, increased cholesterol secretion in obese subjects could not be fully explained by the amount of calories they ingested to maintain stable weight. It is concluded that obesity is characterized by excessive hepatic secretion of cholesterol, which results in supersaturated bile.

0633 COUNTERFEIT CHOLECYSTITIS: A COMMON DIAGNOSTIC PROBLEM. (Eng.) Halasz, N. A. (Univ. California, San Diego Sch. Medicine, 225 West Dickinson St., San Diego, CA 92103). *Am. J. Surg.* 130(2):189-193; 1975.

A retrospective study was made of 238 patients admitted in a 5-yr period with a diagnosis of acute cholecystitis. The diagnosis was confirmed in 191 patients. Of these, 52 underwent operation within 48 hr after admission, 104 had later operations, and 35 had no surgery, but biliary disease was confirmed by radiography or other means. Of the total 238 patients, 47 were ultimately diagnosed with disease other than acute cholecystitis. Among these, five patients underwent exploration with the misdiagnosis of acute cholecystitis. In 18 patients with renal disease, pain initiated in the right kidney or upper ureter. Intrahepatic swelling was present in 6 cases, pancreatitis in 10, pneumonia or pleurisy in 2, appendicitis in 5, and 6 patients had hepatitis. Pre-operative study and interval cholecystectomy are recommended whenever possible to avoid misdiagnosis and unnecessary surgery.

0634 CONTROLLED CLINICAL TRIAL COMPARING EARLY WITH INTERVAL CHOLECYSTECTOMY FOR ACUTE CHOLECYSTITIS. (Eng.) McArthur, P.; Cuschieri, A.; Sells, R. A.; Shields, R. (Dept. Surgery, Univ. Liverpool, Liverpool, England). *Br. J. Surg.* 62(10): 850-852; 1975.

A prospective study is presented of 32 patients with acute cholecystitis in which traditional management (initial conservative treatment with antibiotics followed by elective cholecystectomy) is compared with early cholecystectomy. Of the 17 patients managed conservatively, there was a misdiagnosis in 2. In the remaining 15 patients with acute cholecystitis, 3 required urgent operation because of failure of medical treatment. Of the 15 patients treated by early cholecystectomy, there was a misdiagnosis in 1. Surgery was technically difficult in two patients but cholecystectomy was possible in all. There was no mortality in either group or any complication directly attributable to the biliary surgery. The incidence of minor postoperative complications was only slightly greater in those treated by early operation. The length of postoperative stay was similar in both groups but those treated conservatively spent an average of 11 more days in the hospital. The preliminary results indicate that patients with acute cholecystitis treated by early cholecystectomy spend less time in the hospital and avoid the complications of failed conservative treatment without the added risk of increased postoperative mortality and major complications.

0635 A CONTROLLED TRIAL OF DRAINAGE AFTER CHOLECYSTECTOMY. (Eng.) Gordon, A. B.; Bates, T.; Fiddian, R. V. (Univ. Colorado Medical Center, Denver, CO). *Br. J. Surg.* 63(4):278-282; 1976.

A prospective controlled trial of drainage after cholecystectomy was made in a consecutive series of 143 patients undergoing cholecystectomy. Fifty patients were randomly allocated to a drainage group and a further 50 to a nondrainage group. The remaining 43 patients were drained electively because the common bile duct was explored or because of infection or incomplete hemostasis. There was no significant difference in the incidence of wound infection or other complications between the drainage and nondrainage groups. The duration of postoperative pyrexia, the number of analgesic injections, and the length of postoperative hospital stay were the same in both. One patient in the drainage group had a reactionary hemorrhage from the drain site requiring transfusion. There was no mortality but one patient in the elective drainage group had to be re-explored for a subhepatic abscess. Three patients in this group drained bile from the drain for 3-9 days, but all had a T tube in place. These experiments fail to demonstrate any advantage or disadvantage in draining the gallbladder bed after cholecystectomy.

0636 GALLBLADDER DISEASE: PREVALENCE IN A SOUTH WALES INDUSTRIAL TOWN. (Eng.) Bainton, D.; Davies, G. T.; Evans, K. T.; Gravelle, I. H. (Medical Res. Council Epidemiology Unit [South Wales], 4 Richmond Rd., Cardiff CF2 3AS, U.K.). *N. Engl. J. Med.* 294(21):1147-1149; 1976.

The prevalence of gallstones was determined in a weighted random sample of the specially enumerated population of a South Wales industrial town. In a population of 1442 inhabitants (1043 men, 68.3% response rate; 399 women, 61.2% response rate) examined by cholecystography, the overall prevalence rates were 6.2% for men 45-69 yr of age and 12.1% for women of the same ages. There was no marked increase in prevalence with age in either sex. Symptoms of dyspepsia said to be suggestive of gallstones were found with approximately equal frequency in those with and without gallbladder disease.

0637 LIVER ABNORMALITIES AND GALLSTONES: A PROSPECTIVE COMBINED CLINICAL, HISTOLOGICAL AND SURGICAL STUDY. (Eng.) Triger, D. R.; MacIver, A. G.; Gamlen, T. R.; Wilken, B. J. (Southampton Univ. Hosp., Southampton, England). *Br. J. Surg.* 63(4):272-277; 1976.

A prospective study of 57 patients (41 women and 16 men) coming to elective cholecystectomy for gallstone disease is presented and the clinical, biochemical, and immunological features were correlated with the histological changes in core biopsies of the liver obtained at surgery. Only 13 biopsies were normal. Ten showed changes of acute duct obstruction, 16 showed minimal portal tract abnormalities, and 10 showed moderate portal tract inflammation and scarring. Changes were more marked in male patients. Clinical and biochemical investigations were not useful in predicting histological appearance, apart from cases with jaundice at the time of operation where changes of acute duct obstruction were usually seen. Autoantibodies were present in 50% of cases tested, and all persisted for at least 6 months after surgery. They were more common in patients with marked histological changes. Operative cholangiography was of little use in predicting histological change. These findings suggest that the possibility of gallstones should be considered in the interpretation of any abnormal liver biopsy, irrespective of clinical symptoms or biochemical investigations.

0638 EFFECT OF PRIMARY BILE ACID INGESTION ON BILE ACID METABOLISM AND BILIARY LIPID SECRETION IN GALLSTONE PATIENTS. (Eng.) LaRusso, N. F.; Hoffman, N. E.; Hofmann, A. F.; Northfield, T. C.; Thistle, J. L. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Gastroenterology* 69(6):1301-1314; 1975.

The effects of chenodeoxycholic (chenic) or cholic acid administration on bile acid kinetics, biliary bile acid composition, daily biliary lipid secretion, and fasting-state bile lipid composition were compared in six patients with gallstones. Bile acid kinetics were measured by isotope dilution, and hourly outputs of bile acid, cholesterol, and phospholipid were quantified by duodenal perfusion over 24 hr during a pretreatment period and two randomized treatment periods with chenic acid (7.1-24.5 mg/kg) or cholic acid (8.9-25.8 mg/kg). During chenic acid ingestion, bile contained predominantly chenyl conjugates. During cholic acid ingestion, bile was composed of about equal amounts of cholyl and deoxycholyl conjugates; chenyl conjugates decreased markedly due in part to a 50% decrease in chenic acid synthesis. Total bile acid pool size doubled in half the patients receiving either bile acid. Biliary bile acid composition reflected pool size changes, i.e., during cholic acid treatment, biliary bile acids consisted mainly of cholic acid and its bacterial degradation product, deoxycholic acid. Compared to cholic acid, chenic acid caused decreased cholesterol output with no difference in bile acid or phospholipid output. Therefore, bile unsaturated with cholesterol entered the duodenum for more hr/day during chenic acid ingestion than during the cholic or pretreatment periods. There was no relation among bile acid pool size, bile acid output, and hr/day of supersaturated bile; there was an inverse relation between total pool size and recycling frequency such that bile acid output remained stable over a wide range of pool sizes. Fasting-state gallbladder bile was supersaturated during the cholic and pretreatment periods, but became unsaturated during chenic acid ingestion. However, hr/day of supersaturated bile could not be reliably predicted from the degree of saturation of fasting-state gallbladder bile ($r = 0.62$). The efficacy of chenic acid and the lack of efficacy of cholic acid for gallstone dissolution appear related to their different specific effects on biliary cholesterol secretion and not to any effect on bile acid and phospholipid secretion or bile acid pool size.

0639 INCREASED SULFATION OF LITHOCHOLATE IN PATIENTS WITH CHOLESTEROL GALLSTONES DURING CHENODEOXYCHOLATE TREATMENT. (Eng.) Stiehl, A.; Raedsch, R.; Kommerell, B. (Gastroenterology Unit, Univ. Heidelberg, Heidelberg, Germany). *Digestion* 12(2):105-110; 1975.

The sulfated and nonsulfated lithocholate in bile was determined before and after chenodeoxycholate administration (1.0-1.5 g/day) to 13 patients (aged 55-73 yr) with cholestrol gallstones. Trace amounts of ^{14}C-taurolithocholate and ^{11}C-taurolithocholate sulfate internal standards were added to concentrated bile. In control experiments, four patients were administered i.v. 15 μCi ^{14}C-lithocholate 24 hr before the bile was obtained. Sulfated and nonsulfated ^{14}C-lithocholate conjugates in bile were separated on Sephadex column chromatography. During the treatment period the bile composition changed markedly. Chenodeoxycholate increased from 42.9% of the total bile salts before treatment to 79.3% after 8 weeks of treatment. Ursodeoxycholate increased from 2.3 to 12.6% and lithocholate from 1.1 to 3.3%. In contrast, cholate decreased from 40.3% of the total bile salts to 3.1% and deoxycholate decreased from 12.5 to 2.5%. Less than 5% of chenodeoxycholate, ursodeoxycholate, cholate, and deoxycholate in bile were sulfated esters. In contrast, considerable amounts of lithocholate were sulfated. The sulfation of lithocholate increased from 32.8% of the total lithocholate before treatment to 73.9% after 8 weeks of treatment. Sulfated lithocholate was more rapidly eliminated in feces and urine and was less toxic than the nonsulfated compound. Therefore, the authors conclude that the increase in the sulfation of lithocholate observed in patients with cholesterol gallstones during chenodeoxycholate treatment represents a protective mechanism.

0640 BILE ACIDS IN BILE DURING LONG-TERM CHENODEOXYCHOLIC ACID TREATMENT. (Eng.) Bremmelgaard, A.; Pedersen, L. (Rigshospitalet, Blegdamsvej 9, 2100 Copenhagen O, Denmark). *Scand. J. Gastroenterol.* 11(2):161-165; 1976.

The effect of treatment with 0.50-0.75 g chenodeoxycholic acid/day over 3-4 months on biliary bile acids was studied in four women and one man with radiolucent gallstones. The relative concentrations of conjugated and sulfated bile acids in duodenal bile were measured in the five patients before and during treatment. Lithocholic acid constituted 1.8% of total conjugated and sulfated bile acids before, and 2.6% during treatment. Lithocholic acid was the predominant bile acid in the sulfate fraction in three patients and chenodeoxycholic acid in two. Sulfated bile acids constituted less than 1% of total bile acids and did not increase during treatment. Ursodeoxycholic acid, the other major metabolite of chenodeoxycholic acid, occurred in higher amounts during therapy. The unsaturated bile acid 3β-hydroxy-Δ^5-cholenic acid, which was found exclusively as its sulfate ester, showed a slight fall. The average glycine/taurine conjugation ratio rose from 2.2 to 4.5. The results confirm that profound alterations in the biliary bile acids take place when chenodeoxycholic acid is administered to patients with cholesterol gallstones.

0641 CURRENT STATUS OF HEPARIN DISSOLUTION OF GALLSTONES: EXPERIMENTAL AND CLINICAL OBSERVATIONS. (Eng.) Gardner, B.; Dennis, C. R.; Patti, J. (Downstate Medical Center, 450 Clarkson Ave., Brooklyn, NY 11203). *Am. J. Surg.* 130(3): 293-295; 1975.

Experimental evidence for the use of heparin in bile for the dissolution of gallstones is reviewed. *In vitro* experiments have demonstrated the efficacy of heparin alone and in combination with bile salts for stone dissolution. Clinical experience using a heparinized saline flush in 43 patients with retained gallstones demonstrated disappearance of the stones in 31 of the patients. Seven of the 12 in whom treatment failed were treated for less than a week and underwent reoperation at that time. Failure of the heparin treatment may be related to an inadequate course, a too solidly compacted stone, or heavy calcification. The authors recommend the use of heparin, 25,000 U in 250 ml saline every 8 hr, as a constant, continuous drip for treatment of retained common duct stones as an alternative to early reoperation.

0642 GALLSTONES AND PERNICIOUS ANEMIA. (Dan.) Halver, B. (County Hosp., DK-4930 Maribo, Denmark). *Ugeskr. Laeg.* 137(5):259-261; 1975.

A retrospective study of the frequency of gallstones in 199 patients with pernicious anemia was conducted. Gallstones were found in 15 patients before diagnosis of pernicious anemia and were detected in 63 more patients after the onset of pernicious anemia. The gallstones were symptomatically manifest in 43 of the 63 patients. Autopsies on 18 patients revealed gallstones in 11 cases; the gallbladder had been removed in two patients. The incidence of gallstones was the same in men and women and was highest at around 70 yr of age as opposed to a peak around 50 yr of age in patients without pernicious anemia. Hemolysis and vitamin B_{12} deficiency in pernicious anemia are assumed to be the essential etiological factors in the formation of pigment stones.

0643 POSSIBLE ROLE OF E. coli BETA-GLUCORONIDASE IN BILE STONE FORMATION. (Hun.) Jakab, F.; Vutskits, Zs. (Clinic Surgery II, Semmelweiss Medical Univ., Budapest, Hungary). *Magy. Sebesz.* 27(6):377-381; 1974.

Escherichia coli-free bile samples from 19 choledochotomized patients with gallstones (other than the calcium bilirubinate type) were incubated with *E. coli* to study the role of *E. coli* beta-glucoronidase in gallstone formation. Sediments of 16 of the incubated samples contained calcium bilirubinate. A simultaneous reduction in the calcium and bilirubin contents in the bile was observed, suggesting the incorporation of these substances into calcium bilirubinate. Beta-glucoronidase activity was detected only in samples containing *E. coli*. These findings suggest a possible role of *E. coli* beta-glucoronidase in gallstone formation.

0644 SERUM 5'-NUCLEOTIDASE IN NEONATAL HEPATITIS AND BILIARY ATRESIA. (Eng.) Chen, S.-H.; Lee, T.-C. (Coll. Medicine, Natl. Taiwan Univ., Taipei, Republic of China). *Acta Paediatr. Sin.* 15(4):139-145; 1974.

The diagnostic value of serum 5'-nucleotidase determinations in 20 Chinese infants (aged 5-17 weeks) with neonatal hepatitis (12) and biliary atresia (8), and 13 normal controls (aged 12-26 weeks) for differentiating between biliary atresia and neonatal hepatitis was evaluated. AMP buffered substrate was used to determine 5'-nucleotidase activity in serum (0.2 ml) by measuring the inorganic phosphorous formed. A correction factor for the formation of inorganic phosphorous was determined by incubating serum (0.2 ml) with glycerophosphate buffered substrate. Serum 5'nucleotidase levels (Bodansky U/l) differed significantly in the three groups, i.e., 9.3, 19.9, and 5.3, resp. This study is in agreement with the observation that in infants with congenital extrahepatic biliary obstruction, where bile duct proliferation is a feature, the enzyme levels are markedly raised and are significantly different from those with neonatal hepatitis. This finding is of diagnostic value in differentiating between the two conditions.

0645 ONGOING CIRRHOSIS AFTER SUCCESSFUL PORTICOENTEROSTOMY IN INFANTS WITH BILIARY ATRESIA. (Eng.) Altman, R. P.; Chandra, R.; Lilly, J. R. (Children's Hosp. Natl. Medical Center, 2125

13th St., N.W., Washington, DC 20009). *J. Pediatr. Surg.* 10(5):685-691; 1975.

Eleven of 31 patients treated by porticoenterostomy procedures for extrahepatic biliary atresia were restudied 3-23 months postoperatively by liver biopsy. Three patients were restudied a third time. At the time of biopsy, repeat isotope scan and biochemical determinations of liver function were obtained. The clinical condition of most of these infants was satisfactory. Six of the rebiopsied patients had bilirubins in the normal range, while four had elevations between 1.5 and 3.5 mg/100 ml. In one, the bilirubin was 7 mg/100 ml. In all patients, the rose bengal scan confirmed excretion of isotope by the liver; six were normal and five showed slight-to-moderate retention of isotope at 24-36 hr. Despite absence of clinical jaundice, normal rose bengal scan, and normal liver function studies, eight showed progressive degrees of hepatic fibrosis when compared to the results of the biopsy taken at the time of porticoenterostomy. Two patients showed stable histology and one, after progressing on a second biopsy, had normal liver histology on a third study. Seven patients experienced at least one episode of cholangitis (manifested by a temperature rise and serum bilirubin elevation). In 10 patients, there was complete absence of cholestasis in the specimen. The authors conclude that there are no valid criteria in these 11 patients to predict the progression, stabilization, or improvement; neither age nor histologic pattern at porticoenterostomy affected the outcome. Thus, the authors suggest that until prognostic criteria are available, all infants under 3 months of age should be treated by porticoenterostomy.

0646 BONE CHANGES IN CONGENITAL BILIARY ATRESIA. RADIOLOGIC OBSERVATION OF 8 CASES. (Eng.) Katayama, H.; Suruga, K.; Kurashige, T.; Kimoto, T. (Juntendo Univ. Sch. Medicine, 2-1-1 Hongo, Bunkyo-ku, Tokyo, Japan 113). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 124(1):107-112; 1975.

Roentgenograms of 38 cases of biliary atresia revealed 8 cases (2 boys and 6 girls) of osseous abnormalities. Definte generalized demineralization of bones was found in three cases, metaphyseal abnormalities in five cases, and fractures in four cases. Marked demineralization of bones was seen in cases in which the clinical course was more than 1 yr. There was no good correlation between osseous changes and severity of liver dysfunction.

0647 BILE FLOW AND BILIARY LIPID SECRETION FOLLOWING RELEASE OF BILIARY OBSTRUCTION IN MAN. (Eng.) Lindblad, L.; Hammarsten, J.; Scherstein, T. (Dept. Surgery, Univ. Goteborg, Goteborg, Sweden). *Scand. J. Gastroenterol.* 10(6):633-639; 1975.

To elucidate the relationship between bile acid secretion and the secretion of lecithin and cholesterol in the postcholestatic condition, five patients were studied after release of complete biliary obstruction. Ten patients operated on for uncomplicated gallstone disease served as controls. The secretion of bile acids, which constituted only newly synthesized acids, increased in the postcholestatic period 2.5-22 times. In spite of that, the secretion rate of bile acids was low ($\leq$ 7.5 μmol/min). The pattern of the relationships between bile acid secretion and bile flow and bile acid secretion and lecithin/cholesterol secretion was the same in the postcholestatic patients as in the controls. However, the bile flow showed a higher bile acid dependency in the postcholestatic condition, and the bile acid-independent flow varied considerably in these patients compared with controls. Linear relations between the bile acid and lecithin/cholesterol secretion rates were found. Extrapolation to zero bile acid secretion revealed Y-intercepts, which were not statistically significantly different from zero. Calculations of bile acid/lecithin and bile acid/cholesterol relations in the controls at correspondingly low bile acid secretion rates ($\leq$ 5 μmol/min) gave results similar to those in the study group. The bile was supersaturated with cholesterol in all the postcholestatic patients similar to the condition in the controls at correspondingly low bile acid secretion rates. It is concluded that the bile acids are determinative for the biliary secretion of cholesterol/lecithin even at very low bile acid secretion rates. This conclusion was valid in patients with presumably normal liver function as well as in the early phase after release of severe cholestasis.

0648 MEMBRANEOUS OBSTRUCTION OF THE COMMON BILE DUCT. (Eng.) Pinter, A.; Pilaszanovich, I.; Schafer, J.; Weisenbach, J. (No affiliation given). *J. Pediatr. Surg.* 10(5):839-840; 1975.

A case of membranous atresia of the common bile duct in a 32-day-old male child with a 22-day history of jaundice is presented. On admission, the liver was found to extend 1 cm below the costal margin. Stools were white, the urine was dark, and the bile was strongly positive. Total serum bilirubin was 11.8 mg/100 ml, direct 8.7 mg/10 ml. At laparotomy, the liver was mildly enlarged and of slightly greenish color, and the gallbladder was almost empty. A cholangiogram revealed that the intrahepatic bile ducts, the tortuous ducts, the fine cystic duct, and the common bile duct ended blindly behind the duodenum. There was no passage into the duodenum. A membrane located at the level of the ampulla of Vater prevented a rubber probe from entering the small intestine. The membrane was incised and stretched, and a thin catheter was introduced into the opening of the common bile duct and passed through the membrane into the duodenum. The other end of the catheter was brought out through the abdominal wall. During the first 3 postoperative days the bile was discharged via the catheter, and later it was passed with the normal enteral circulation. By the 10th day the jaundice had disappeared, the stools became green and later yellow in color, and total serum bilirubin was 1.5 mg/100 ml, direct 1.0 mg/ml. At the age of 18 months, the child had not had jaundice or attacks of cholangitis since surgery. The authors conclude that this is the first case of membranous atresia of the common bile duct reported in the literature.

0649 THE EFFECT OF EXTERNAL DRAINAGE OF BILE ON CHOLESTEROLEMIA. (Eng.) Hankiewicz, J.; Rudzka, E. (First Clinic Internal Diseases, Silesian Acad. Medicine, ul. Reymonta 8, PL-40-029 Katowice, Poland). *Atherosclerosis* 22(2):313-315; 1975.

The effect of bile secretion on serum cholesterol concentration was studied in 50 patients who had undergone biliary duct surgery. Total and esterified cholesterol concentrations in samples of serum and bile were determined at the time of bile drainage from the common bile duct. The daily amount of drained bile in these patients averaged 339 ml for 5 consecutive days after surgery. From day 5 to day 15, drainage averaged 342 ml/day. The total bile concentration of cholesterol up to day 15 and from day 5 to day 15 averaged about 240 mg/100 ml (range, 30-705 mg/100 ml), and the esterified fraction was about 157 mg/100 ml. The excretion of cholesterol in bile in both postoperative periods averaged 725 and 881 mg/day. The total serum cholesterol concentration on the day of surgery ranged from 153-500 mg/ml. During external bile drainage there was a significant decrease in cholesterolemia to about 30%. A direct relation was found on day 5 between the decrease of serum cholesterol and the amount of cholesterol excreted in bile. There was also a direct relation between the concentration of total and esterified cholesterol in serum and the concentration of these components in bile. These data suggest that the loss of cholesterol with the bile was probably compensated for by an increase of its synthesis.

0650 RENAL FAILURE IN OBSTRUCTIVE JAUNDICE--PATHOLOGIC FACTORS. (Eng.) Wardle, E. N. (Royal Victoria Infirmary, Newcastle-upon-Tyne, NE1 4LP, U.K.). *Postgrad. Med. J.* 51(598):512-514; 1975.

The factors involved in the pathogenesis of acute renal failure in obstructive jaundice are summarized. In a patient with obstructive jaundice, preliminary dehydration combined with the toxic effects of free bilirubin and serum bile acids, together with factors that cause inhibition of fibrinolysis, determine a high degree of renal susceptibility to ischemia. Evidence from animals and man suggests that intravascular coagulation determined by endotoxemia from the obstructed biliary system occurs at the onset of acute renal failure. Endotoxin is unique in being able to produce all those factors that separately cause a primary increase of renal arteriolar constriction. The author suggests that the evidence is consistent with the hypothesis that endotoxin is the cause of the majority of cases of acute renal failure in man.

0651 ANTIBIOTIC TREATMENT OF BILIARY SEPSIS. (Eng.) Keighley, M. R. B.; Drysdale, R. B.; Quroaishi, A. H.; Burdon, D. W.; Alexander-Williams, J. (Dept. Surgery, Queen Elizabeth Hosp., Birmingham, B12 2TH England). *Surg. Clin. N. Am.* 55(6):1379-1390; 1975.

Antibiotic therapy for the control of established biliary sepsis and the prevention of postoperative complications among patients with infected bile at operation is reviewed. Biliary sepsis is usually associated with some degree of obstruction in the biliary tract. *Escherichia coli* is the most commonly identified microorganism, occurring in 31% of 231 patients undergoing biliary operations. The incidence of wound sepsis in patients in whom the bile is sterile or infected is 13 or 35%, resp. Management of patients with biliary sepsis falls into two categories; first, the use of prophylactic chemotherapy for patients requiring biliary operations and second, the choice of an antibiotic in patients with acute cholecystitis or unresolving cholangitis. In either case the presence and type of organism must be determined before or at operation; blood cultures and a duodenal fluid sample are taken before antibiotic therapy. Prophylactic chemotherapy is justified only when the bile is infected at operation. If gram-positive organisms are identified, ampicillin is recommended while gentamicin is recommended for the treatment of gram-negative bacteria. If surgery is needed, antibiotics are continued, modified only if operative bile cultures indicate the presence of a resistant organism. However, if there is an obstruction, therapeutic levels often cannot be achieved in the bile. It is concluded that serum concentrations of a suitable antimicrobial are required to prevent and control the systemic manifestations of biliary sepsis.

0652 SPONTANEOUS INTERNAL BILIARY FISTULAS. (Eng.) Patrassi, N.; Basoli, A.; Loriga, P.; Blandamura, V.; Carboni, M. (Univ. Rome Medical Sch., Policlinico Umberto I, 00161 Rome, Italy). *Am. J. Gastroenterol.* 64(3):181-186; 1975.

The etiology, diagnostic investigations, and surgical procedures performed on 58 patients with spontaneous internal biliary fistulas are reported. Cholelithiasis and peptic ulcer were presumed to be the cause of fistula in 53 and 5 patients, resp. Preoperative diagnosis was established on 31 patients, while the remaining 27 fistula were found incidentally at surgery. Surgical treatment included a wide variety of operations performed on the basis of the pathologic features of fistula. Overall mortality rate was 5%, and morbidity was 13%. The unsatisfactory results of the surgical treatment of internal biliary fistulas indicate that early cholecystectomy should be performed in all patients with cholelithiasis.

0653 LONG TERM TRANSHEPATIC INTUBATION FOR HILAR HEPATIC DUCT STRICTURES. (Eng.) Cameron, J. L.; Skinner, D. B.; Zuidema, G. D. (Johns Hopkins Medical Inst., Baltimore, MD). *Ann. Surg.* 183(5):488-495; 1976.

A technique for repairing benign high hilar hepatic

LIBRARY U. OF I.

duct strictures using transhepatic intubation with a large bore silastic stent in 10 patients is described. In nine instances, the stricture involved the common hepatic duct and in one, the right and left hepatic ducts. Nine of the strictures followed cholecystectomy; one followed the primary repair of a gun shot wound to the hepatic duct. Hepaticojejunostomies were created and the transhepatic silastic stent was left in place for 6 months in one patient, and for 12 months in eight patients. In one patient the silastic stents remained in place. There were no treatment failures. All patients were healthy and at full activity from 1 yr, 3 months to 6 yr, and 6 months from the time of repair (average 3 yr, 5 months), resp. In the nine patients whose stents were removed, the serum bilirubin levels were normal. There were no episodes of cholangitis following repair. The authors recommend this method of repair using long-term transhepatic silastic stents for all high hilar hepatic duct strictures.

0654 IDIOPATHIC SCLEROSING CHOLANGITIS. PATHOPHYSIOLOGIC OBSERVATIONS. (Eng.) Douglass, H. O., Jr. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY 14263). *Am. J. Surg.* 130(1): 82-87; 1975.

Selective hepatic arteriography and umbilical portography in a 50-yr-old man with idiopathic sclerosing cholangitis revealed uneven distribution of blood flow through the liver. The majority of the contrast media was in the central portion of the liver. Mild portal hypertension was present. The stenotic biliary tree offered no unusual resistance to the passage of dye from the main biliary radicals into the duodenum. T tube drainage dramatically relieved pruritis, but clinical improvement with weight gain, disappearance of jaundice, and reduction of portal pressure did not occur until after the administration of steroids. After 1 yr of steroid therapy, biopsy showed a reduction in the periportal inflammatory reaction and lessening of the diffuse stenosis of the biliary tree. It is suggested that sclerosing cholangitis accompanying biliary calculous disease and that accompanying ulcerative colitis may be a variant of a common pathogenic process.

0655 HEREDITY AND DISEASES OF THE EXTRA-HEPATIC BILE DUCTS. (Fre.) Paris, M. J. (No affiliation given). *Bordeaux Med.* 8(7):777-782; 1975.

0656 BIOLOGICAL CHARACTERISTICS OF Pseudomonas pyocyanea ISOLATED FROM BILE IN CHRONIC INFLAMMATORY DISEASES OF THE GALLBLADDER AND BILE DUCTS. (Rus.) Ordzhonikidze, Z. V.; Kurashvili, V. GENERAL

0689 CHOLECYSTOKININ METABOLISM IN MAN AND DOGS. (Eng.) Thompson, J. C.; Fender, H. R.; Ramus, N. I.; Villar, H. V.; Rayford, P. L. (Univ. Texas Medical Branch, Galveston, TX 77550). *Ann. Surg.* 182(4):496-504; 1975.

A sensitive, specific, and reproducible radioimmunoassay for cholecystokinin (CCK) was developed with which basal levels of CCK of between 400-800 pg/ml were measured in patients with diabetes, duodenal ulcer disease, in normal subjects, and in normal dogs. After a meal, circulating levels of CCK rose to 1000-1200 pg/ml in human subjects. Release of CCK was more rapid in diabetic and duodenal ulcer patients than in normal subjects, but elevated postprandial levels persisted much longer in normal subjects. Patients with the Zollinger-Ellison syndrome had elevated values of cholecystokinin, which rose after a meal. Lack of correlation between elevated basal levels of gastrin and CCK in patients with the Zollinger-Ellison syndrome suggested that the hypercholecystokininemia may be absolute. The disappearance half-time of exogenous CCK was about 2.5 min in normal subjects as well as in diabetic and duodenal ulcer patients. In dogs, there was no uptake of basal levels of cholecystokinin by the kidney; on infusion of exogenous CCK-33, the kidney extracted 43% of the total CCK presented and 56% of the integrated CCK. It is concluded that: 1) circulating basal and postprandial levels of CCK may be measured in a reproducible fashion, 2) postprandial release of CCK is more rapid in diabetic and duodenal ulcer patients than in normal man, 3) the disappearance half-time of exogenous CCK in man and dogs is 2.5 min, and 4) the kidney is a major site for uptake of CCK.

0690 LOPERAMIDE ANTAGONISM OF CASTOR OIL-INDUCED DIARRHEA IN RATS: A QUANTITATIVE STUDY. (Eng.) Awouters, F.; Niemegeers, C. J. E.; Kuyps, J.; Janssen, P. A. J. (Janssen Pharmaceutica Res. Lab., B-2340 Beerse, Belgium). *Arch. Int. Pharmacodyn. Ther.* 217(1):29-37; 1975.

The occurrence of intestinal evaluations and the amount of body constituents lost in stools after a single administration of castor oil (1 ml) to fasting female Wistar rats, untreated rats, and rats pretreated with loperamide were studied. The time-course of castor oil-induced diarrhea in fasted rats was quantified by weighing stools every 15 min for 8 hr after the challenge and then after 24 hr. Diarrhea began within 1 hr as a series of rapidly occurring evacuations over 20-40 min. The mean weight of these stools was 5.7 g; later irregular evacuations increased the weight to 9.4 g at 8 hr. The area of individual time-weight diagrams had a median value of 432 U. Pretreatment with 0.16 mg/kg of loperamide significantly decreased the area of similarly obtained diagrams; 0.31 mg/kg caused a 50% reduction. It is suggested that this action of loperamide may involve reduction in the severity of inflammatory changes in the intestinal wall.

0691 THE ROLE OF INTESTINAL GAS IN FUNCTIONAL ABDOMINAL PAIN. (Eng.) Lasser, R. B.; Bond, J. H.; Levitt, M. D. (Veterans Admin. Hosp., 54th St. and 48 Ave. South, Minneapolis, MN 55417). *N. Engl. J. Med.* 293(11):524-526; 1975.

A washout technique with intestinal infusion of an inert gas mixture was used to study the relation of gas to functional abdominal symptoms. The volume of gas in the intestinal tract (176 ml) of 12 fasting patients with chronic complaints of excess gas did not differ significantly from that of 10 controls (199 ml). Similarly, there was no difference in the composition or accumulation rate of intestinal gas. However, more gas tended to reflux back into the stomach in patients who complained of abdominal pain during infusion of volumes of gas well tolerated by controls. Six patients with severe pain during the study had intestinal transit times of gas (40 min) that were significantly longer than those of the control group (22 min). The results indicate that complaints of bloating, pain, and gas may result from disordered intestinal motility in combination with an abnormal pain response to gut distention rather than from increased volumes of gas.

0692 THERAPEUTIC TRANSLUMINAL ARTERIAL EMBOLIZATION FOR BLEEDING IN THE UPPER PART OF THE GASTROINTESTINAL TRACT. (Eng.) Katzen, B. T.; McSweeney, J. (St. Vincent's Hosp. and Medical Center, New York, NY). *Surg. Gynecol. Obstet.* 141(4): 523-527; 1975.

e value of transluminal arterial embolization of bleeding site in the upper part of the gastro-testinal (GI) tract in two patients representing poor operative risk and in whom vasopressor thera- had failed was investigated. Case 1, a 39-yr- d man, presented with bright red hematemesis and lena. Aortogram revealed multiple areas of con- ast extravasation and selective hepatic arterio- aphy demonstrated considerable extravasation in e duodenal bulb and sweep. Selective superior senteric artery injection demonstrated bleeding om the site. Duodenotomy revealed two 3 cm cerations. Following gastroduodenal artery gation, vagotomy, and pyloroplasty the patient mained relatively stable, but slow oozing occurr- over the next 2-3 days. Subsequently, massive eeding began. Catheter perfusion of vasopressin .2 to 0.3 U/min) did not produce any significant ange in the extent of extravasation. After a 2 x mm piece of absorbable gelatin sponge was inserted perselectively into the inferior pancreaticoduo- nal artery, repeat angiograms demonstrated occlu- on of the inferior pancreaticoduodenal artery with further extravasation. Case 2, a 66-yr-old man, perienced an episode of massive hemorrhage in the per part of the GI tract 2 weeks after a right patic lobectomy for cholangiocarcinoma of the ver. Embolization of the left gastric artery th gelatin sponge was performed. There was an mediate cessation of bleeding, but 24 hr later, other massive hemorrhage in the upper part of the tract developed. Extensive subtotal gastrectomy s performed. The patient recovered from the GI eeding but subsequently developed hematobilia. peated selective arteriography failed to elucidate e site of bleeding; however, the catheter was left the common artery for subsequent vasopressin fusions. The authors conclude that transluminal bolization represents an alternative method in or-operative risk patients and in those cases ere vasopressor therapy has failed. Potential sks include intestinal ischemia and may vary with e anatomic site.

93 GASTRIC LESION IN DERMATITIS HERPETIFORMIS. (Eng.) O'Donoghue, D. P.; Lan- ster-Smith, M.; Johnson, G. D.; Kumar, P. J. . Bartholomew's Hosp., London, England EC1A , England). *Gut* 17(3):185-188; 1976.

ients (33, 24 men and 9 women) with dermatitis rpetiformis (DH) were studied with regard to stric morphology and pentagastrin stimulated d secretion. In addition, the sera of DH pa- nts and 30 healthy controls (14 men and 16 men) were screened for gastric parietal cell anti- ly by indirect immunofluorescence. Five of 33 ients had parietal cell antibody in their sera, ereas the antibody was not evident in 30 healthy trols of comparable age distribution. The tological and functional state of their gastric osa were studied in 15 of the patients. Atrophic tritis was found in all 5 whose sera contained tric parietal cell antibody and in 3 of 11 pa- nts with no antibody in their sera. In addition, re was marked impairment of acid secretion in DH group as a whole, but apart from one patient with overt pernicious anemia, there was no evidence of malabsorption of vitamin B_{12}. The results demonstrate an increased incidence of gastric parietal cell antibodies, confirming previous findings. However, the results differ with the usual female preponderance reported for this antibody as four of five patients with the antibody were men.

0694 PROTRACTED DIARRHEA AND MALNUTRITION IN INFANCY: CHANGES IN INTESTINAL MORPHOLOGY AND DISACCHARIDASE ACTIVITIES DURING TREATMENT WITH TOTAL INTRAVENOUS NUTRITION OR ORAL ELEMENTAL DIETS. (Eng.) Greene, H. L.; McCabe, D. R.; Merenstein, G. B. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37232). *J. Pediatr.* 87(5):695-704; 1975.

Two therapeutic regimens were compared in 16 infants with protracted diarrhea and malnutrition. Eight patients were treated with total parenteral nutrition (TPN) given via a central vein (group A); the remaining eight patients received a combination of dilute parenteral nutrients given in a peripheral vein plus continuous enteral feedings of an elemental diet (group B). All patients recovered, although two infants in group B were switched to TPN treatment after a poor response to the elemental diet. Intestinal biopsies were performed before treatment, after 2-3 weeks of TPN or elemental diet, and after 2-3 weeks of Nutramigen (containing sucrose, dextrose, glucose, vegetable oil, and casein hydrolysate) feedings. Before treatment, all patients had atrophic changes in the jejunal epithelium and deficient disaccharidase and trypsin activities. The second biopsy showed morphologic recovery in all patients, incomplete recovery of lactase and trypsin in both treatment groups, and complete recovery of sucrase and maltase activities only in group B patients. The third biopsy showed normal morphology and complete recovery of all enzymes measured. The mean number of hospital days was 46 ± 4.8 for group A and 34 ± 1.6 for group B ($p<0.05$), suggesting that patients given enteral feedings early tend to have a more rapid return of intestinal function and of some intestinal enzymes.

0695 NECROTIZING ENTEROCOLITIS IN LOW-BIRTH-WEIGHT INFANTS FED AN ELEMENTAL FORMULA. (Eng.) Book, L. S.; Herbst, J. J.; Atherton, S. O.; Jung, A. L. (Dept. Pediatrics, Univ. Utah, Salt Lake City, UT). *J. Pediatr.* 87(4):602-605; 1975.

A study was conducted in two groups of eight low-birth-infants (less than 1,200 g) to determine the nutritional efficacy as well as the incidence of necrotizing enterocolitis of a standard cow milk formula (0.8 cal/ml containing 2.8 g cow mild protein, 3.7 g corn oil, and 9.1 g sucrose and lactose per 100 ml) versus an elemental formula (0.67 cal/ml containing 2.2 g casein hydrolysate, 2.8 g medium-chain triglycerides, and 8.8 g glucose per 100 ml). The clinical status of the two groups was similar. Seven of eight infants fed the elemental formula and two of eight fed the standard cow milk formula developed necrotizing enterocolitis. The hypertonicity of the elemental diet may have contributed to the increased incidence of necrotizing enterocolitis in infants fed this formula.

0696 HUMAN REOVIRUS-LIKE AGENT AS THE MAJOR PATHOGEN ASSOCIATED WITH "WINTER" GASTROENTERITIS IN HOSPITALIZED INFANTS AND YOUNG CHILDREN. (Eng.) Kapikian, A. Z.; Kim, H. W.; Wyatt, R. G.; Cline, W. L.; Arrobio, J. O.; Brandt, C. D.; Rodriguez, W. J.; Sack, D. A.; Chanock, R. M.; Parrott, R. H. (Natl. Inst. Health, Bldg. 7, Bethesda, MD 20014). *N. Engl. J. Med.* 294(18):965-972; 1976.

A human reovirus-like agent was found in the stools of 42% of 143 infants and young children hospitalized with acute gastroenteritis between January 1974 and June 1975. The occurrence of the agent among parent contacts of the patients and the role of labile toxin-producing *Escherichia coli* in infantile gastroenteritis were also examined. Half the patients studied by electron microscopy and serologic techniques had evidence of infection with the agent. The infection had a seasonal pattern; 59% of those admitted during the cooler months (November-April) shed the agent, with a peak of 78% in December 1974 and January 1975, combined. None of the patients admitted during the warmer months (May-October) shed the agent. None of 275 *E. coli* isolates from 32 patients with diarrhea produced heat-labile enterotoxin, whereas 17 of the 32 had evidence of infection with the reovirus-like agent. In addition, 14 of 40 parents of 37 patients with diarrhea associated with the agent were also infected, but most infections were inapparent. This agent appears to be the major cause of diarrheal illness in children during the cooler months.

0697 SEROTONIN METABOLISM IN CHILDREN WITH KWASHIORKOR. (Eng.) Teotia, M.; Teotia, S. P. S. (L.L.R.M. Medical Coll., Meerut [U.P.], India). *Am. J. Clin. Nutr.* 28(11):1284-1288; 1975.

Intestinal fat absorption, serum 5-hydroxytryptamine (5-HT) level, and 24-hr urinary excretion of 5-hydroxyindoleacetic acid (5-HIAA) were studied in 13 children with kwashiorkor and in 10 matched (age, sex, socioeconomic strata) healthy controls. Eight of the 13 children with kwashiorkor who also had steatorrhea showed raised plasma serotonin levels in parallel with the high urinary excretion of 5-HIAA. In five children with kwashiorkor who showed normal intestinal fat absorption, the serum 5-HT and urinary 5-HIAA levels were comparable to controls. After therapy, concurrent with clinical and biochemical recovery, the intestinal absorption of fat improved and serum 5-HT concentration and the urinary excretion of 5-HIAA returned to normal range. This suggests that the deranged serotonin metabolism in these cases was secondary to the protein calorie deficiency.

0698 GASTROINTESTINAL INVOLVEMENT IN SYSTEMIC MASTOCYTOSIS. (Eng.) Ammann, R. W.; Vetter, D.; Deyhle, P.; Tschen, H.; Sulser, H.; Schmid, M. (Div. Gastroenterology, Univ. Zurich, Zurich, Switzerland). *Gut* 17(2):107-112; 1976.

Histamine levels were determined in the serum and gastric biopsy specimens of four consecutive patients with systemic mastocytosis to test the hypothesis that the presence of urticaria-like lesions associated with a high tissue histamine content is an important factor responsible for the gastrointestinal symptoms in many of these patients. One patient had a malabsorption syndrome with only minor histological changes of the intestinal mucosa. Another patient with ulcer diathesis had a gastric secretory pattern resembling Zollinger-Ellison syndrome. Serum gastrin and histamine levels were consistently normal in all patients. Endoscopy of stomach and colon disclosed urticarial-like papules either spontaneously or after topical provocation in all patients. No increase of mast cells was found in multiple mucosal biopsies. A markedly increased gastric tissue content of histamine was found, however, in the three patients studied. The findings suggest that urticaria-like lesions associated with a high tissue content of histamine may be more important than hyperhistaminemia in causing the various gastrointestinal symptoms.

0699 EFFECT OF UROGASTRONE IN THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Elder, J. B.; Ganguli, P. C.; Gillespie, I. E.; Delamore, W. I.; Gregory, H. (Royal Infirmary, Manchester, England). *Lancet* 2(7932):424-427; 1975.

The effects of human urogastrone (0.25 μg/kg/hr i.v.) in four male patients (aged 22-40 yr) with Zollinger-Ellison syndrome (ZES) and in four healthy male control subjects (aged 26-42 yr) were investigated. Gastric juice aspirates, recordings of the skin temperature, radial pulse rate, and blood pressure were taken at 15-min intervals. Subjective comments on any discomforts felt by the patients before, during, and after urogastrone infusion were noted, as were general clinical observations of skin color, sweating, or restlessness. Urogastrone administration to ZES patients decreased gastric acid volume and concentration, and reduced basal acid output by 50-82%. The concentration of intrinsic factor and pepsin in gastric juice increased by 60-300%. Peak plasma gastrin concentration increased by 127-164% of basal concentration. A significant negative correlation between increase in plasma gastrin concentration and decrease in acid output was observed. No significant alteration in any clinical, hematological, or biochemical measurement was found during or after the urogastrone infusion in either the control or ZES subjects. The ZES patients had complete relief of ulcer pain shortly after the urogastrone infusion and this persisted for up to 24 hr. The authors conclude that urogastrone inhibits the endogenously stimulated acid hypersecretion in ZES.

GENERAL

Regional Enteritis

0756 AN EVALUATION OF THE 'BREATH TEST' IN CROHN'S DISEASE. (Eng.) Lenz, K. (Div. Gastroenterology, Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(6):665-671; 1975.

The 1-(^{14}C)-glycine-glycocholic acid breath test was evaluated in 10 normal subjects and in 38 patients with Crohn's disease. Twenty-six had been subjected to ileal resection (10-180 cm), and 12 had not undergone surgery. Cecal resection or right-sided hemicolectomy was also performed on 20 patients and subtotal colectomy on 6. The ^{14}C-excretion in the breath was abnormally elevated in only 16 of the 38 patients with Crohn's disease. When ^{14}C-excretion in both breath and feces were combined, the test was found to be correlated with the activity of the disease in nonoperated cases, whereas all resected patients had bile acid malabsorption. It is concluded that the breath test is useless in Crohn's disease without concomitant measurement of the radioactivity in stools. The fecal ^{14}C-excretion was correlated with the extent of ileal resection and with the extent of colonic resection, whereas the ^{14}C-excretion in breath was independent of the type of operation performed. The breath test was found to be a more sensitive assay for ileal dysfunction than the duodenal bile acid concentration and the vitamin B_{12} absorption. No correlation with an elevated glycine/taurine ratio and an abnormal bacterial growth was found.

0757 IMMUNOLOGICAL STUDIES IN PATIENTS WITH CROHN'S DISEASE. (Eng.) MacPherson, B. R.; Albertini, R. J.; Beeken, W. L. (Dept. Pathology and Medicine, Medical Alumni Bldg., Univ. Vermont, Burlington, VT). *Gut* 17(2):100-106; 1976.

Immunological parameters were investigated in 38 patients with Crohn's disease using skin tests with dinitrochlorobenzene and a battery of common skin test antigens, lymphocyte transformation with phytohemagglutinin (PHA) and pokeweed mitogen, serum immunoglobulins, and absolute lymphocyte counts. Crohn's disease patients were divided into two groups, those treated and not treated with immunosuppressive drugs. The latter group was subdivided into patients with active and inactive disease. Immunosuppressed patients with Crohn's disease did not develop sensitivity to dinitrochlorobenzene and had mildly depressed skin test reactivity to common skin test procedures. Nonimmunosuppressed patients with active Crohn's disease also reacted less frequently to common skin test antigens, but 16 of 17 such patients developed sensitivity to dinitrochlorobenzene. Lymphocyte transformation with PHA and pokeweed mitogen was normal in all groups of patients with Crohn's disease. However, when suboptimal incubation periods were used with PHA stimulation, there was a significant difference between Crohn's disease patients and controls. Serum immunoglobulin levels and absolute lymphocyte counts were normal in all Crohn's disease patients. It is concluded that immunity in Crohn's disease is qualitatively normal.

0758 CARCINOMA COMPLICATING CROHN'S DISEASE: REPORT OF SEVEN CASES AND REVIEW OF THE LITERATURE. (Eng.) Lightdale, C. J.; Sternberg, S. S.; Posner, G.; Sherlock, P. (Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, New York, NY 10021). *Am. J. Med.* 59(2):262-268; 1975.

Case reports are presented for seven patients with carcinoma complicating regional enteritis. The first three patients (men, aged 56, 53, and 49 yr, resp.) had carcinoma of the small intestine. All had diarrhea of long duration (23, 25, and 15 yr, resp.). The distal ileum and ascending colon were resected in the first patient, and an ileocolostomy was performed. Postoperatively he received 5-fluorouracil for adenocarcinoma. The terminal loops of the ileum and the mesentery were resected in the second patient and an end-to-end ileocolic anastomosis was performed. Pathological samples showed infiltrating adenocarcinoma of the ileum. Postoperatively he received prednisone and intermittent diphenoxylate hydrochloride with atropine sulfate. The last patient in this group had widespread malignant involvement of the gastrointestinal tract. After palliative surgery, he was treated with 5-fluorouracil. The last four patients (a woman and 3 men; aged 50, 30, 26, and 56 yr, resp.) all developed colonic adenocarcinoma with regional enteritis. Fistulas developed in two, and obstructions in two. The first patient received radiotherapy and abdominoperineal resection. The other three had resections of the diseased areas. No evidence of cancer was seen in three of the seven patients, 3, 6, and 7 yr after surgery, resp. No evidence of cancer was seen at autopsy in one patient 16 months after surgery. The remaining three cases had rapidly developing widespread intra-abdominal metastases. While these data do not inlicate a causal relation between regional enteritis and adenocarcinoma, early detection and resection of the cancer is stressed.

0759 DESTRUCTIVE MONARTHRITIS AND GRANULOMATOUT SYNOVITIS AS THE PRESENTING MANIFESTATIONS OF CROHN'S DISEASE. (Eng.) Frayha, R.; Stevens, M. B.; Bayless, T. M. (Johns Hopkins Univ. Sch. Medicine, Baltimore, MD). *John Hopkins Med. J.* 137(4):151-155; 1975.

Case reports of a 22-yr-old woman (case 1) and a 14-yr-old boy (case 2) with Crohn's disease with radiological evidence of altered articular cartilage and subchondral bone are presented. In case 1, radiographic examinations of the right hip showed narrowing of the joint space. A barium enema radiographic examination demonstrated nodular mucosal densities in the splenic flexure and transverse colon with loss of cecal haustrations. A small bowel radiographic examination showed fixation and increased bowel wall thickness in the ileocecal region. The radiologic findings were consistent with Crohn's disease. Prednisone (40 mg four times/day) and salicylazosulfapyridine (3 g four times/day) resulted in prompt symptomatic improvement. In case 2, radiographic examination of the left knee showed subchondral erosion of the lateral condyle. Histologically there was a diffuse synovitis with noncaseating granulomatous inflammation. A small bowel radiographic examination demonstrated distal ileal and cecal thickness and irregularity with a cobblestoned appearance of the terminal ileum. Progressive improvement followed chemotherapy. Thus, in both individuals where intestinal symptoms were not prominent, the development of monarthritis led to the discovery of the underlying inflammatory bowel disease. The presence of granulomata in the synovium suggests that the same process involved in granulomatous enteritis may also be responsible for some of the extraintestinal manifestations of Crohn's disease.

0760 THE LONG-TERM PROGNOSIS OF ILEORECTAL ANASTOMOSIS AND PROCTOCOLECTOMY IN CROHN'S DISEASE. (Eng.) Weterman, I. T.; Pena, A. S. (Univ. Hosp., Leiden, Netherlands). *Scand. J. Gastroenterol.* 11(2):185-191; 1976.

The long-term prognosis of ileorectal anastomosis and proctocolectomy in Crohn's disease was studied in 226 patients. Twenty-one of the 60 patients with almost total colonic involvement were treated by an ileorectal anastomosis between 1957 and 1973. Sixteen patients underwent a proctocolectomy between 1948 and 1972. Five of them had previously had an ileorectal anastomosis and were therefore included in both groups. The patients were followed up for a mean period of 8.3 yr. There was no surgical mortality in the group of ileorectal anastomosis, whereas in the group of proctocolectomy there was one early and one late postoperative death. The recurrence rate after ileorectal anastomosis was 75%, but 40% of these cases responded well to conservative treatment and have not required further surgery. The recurrence rate after proctocolectomy was 31%. The results concerning mortality, morbidity, and recurrence are compared with reports in the literature.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

LIBRARY U. OF I.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
amp	ampere
ATP	adenosine triphosphate
A	angstrom
BSP	sulfobromophthalein
C	degrees centigrade
cal	calories
cc	cubic centimeter
cm	centimeter(s)
dl	deciliter
DNA	deoxyribonucleic acid
ED$_{50}$	median effective dose(s)
EDTA	ethylenediamine tetraacetic acid
e.g.	for example
EEG	electroencephalogram
ESR	erythrocyte sedimentation rate
g	gram(s)
μg	microgram(s)
Hz	Hertz
hr	hour(s)
i.m.	intramuscular
i.p.	intraperitoneal
IU	international unit(s)
i.v.	intravenous
kcal	kilocalorie(s)
kg	kilogram(s)
K$_m$	Michaelis constant
LD$_{50}$	median lethal dose(s)
LDH	lactic acid dehydrogenase
m	meter(s)
M	molar; mole(s)
mM	millimolar; millimole(s)
μM	micromolar; micromole(s)
ma	milliampere(s)
mCi, μCi	milli-, microcurie(s)
mEq	milliequivalent(s)
mg	milligram(s)
ml, μl	milli-, microliter(s)
mm	millimeter(s)
mOsm	milliosmolar; milliosmeter(s)
msec	millisecond(s)
mV	millivolt(s)
min	minute(s)
MTD	maximum tolerated dose
NAD	nicotinamide adenine dinucleotide
NADH	reduced nicotinamide adenine dinucleotide
NADP	nicotinamide adenine dinucleotidephosphate
NADPH	reduced nicotinamide adenine dinucleotidephosphate
ng	nanogram (10^{-9})
nm	nanometer(s)
Pa	ambient pressure
PAS	periodic acid - Schiff
pg	picogram (10^{-12})
pgEq	picogram equivalent(s)
p.o.	orally
ppb	parts per billion
ppm	parts per million
r	Roentgen
RBC	red blood cells (erythrocytes), red blood count
resp.	respectively
RNA	ribonucleic acid
s.c.	subcutaneous
sec	second(s)
SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

)771 MORPHOGENESIS OF FETAL RAT DUODENAL VILLI.
(Eng.) Mathan, M.; Moxey, P. C.; Trier,
. S. (Harvard Medical Sch., Boston, MA 02115).
m. J. *Anat.* 146(1):73-92; 1976.

he histogenesis of villi from the primitive mucosa,
ined by undifferentiated epithelial cells, in the
uodena of 15-to 19-day-old Sprague-Dawley rat fetuses
as studied by light and electron microscopy. The
uodenal epithelium of 15- to 18-day-old fetuses was
tratified. Distinctive junctional complexes as-
ociated with membrane-bounded vesicles and cilia-
ike structures were seen in the deeper epithelial
ayers at 15 and 16 days. Small lumina, designated
secondary lumina," lined with a variable number of
icrovilli developed between epithelial cells at
hese junctional complexes during the 16th-18th
ays. Degenerative changes and exfoliation of
uperficial epithelial cells were obvious in 17-
nd 18-day-old fetuses. In 18-day-old fetuses, ag-
regates of mesenchyme invaginated the basal aspect of
he stratified epithelium. Concomitantly, the number
f epithelial layers overlying these mesenchymal pro-
ections was decreased. In 19-day-old fetuses, well
ormed, short duodenal villi lined by a single colum-
ar epithelium, which included goblet and endocrine
ells, were evident. Injection of ferritin into the
ain duodenal lumen of 17-day-old fetuses failed to
eveal continuity between the main duodenal lumen
nd the secondary lumina. However, continuity be-
ween many secondary lumina and the main lumen was
emonstrated in 18-day-old fetuses. Thus, major
rphological features associated with villus forma-
ion in fetal rat duodenum include: formation of
ny secondary lumina in primitive stratified
pithelium; eventual fusion of these lumina with the
in duodenal lumen, by their continued growth,
upled with exfoliation of degenerating super-
cial layers; and upward growth of mesenchyme to the
men, as cell exfoliation and expansion of secondary
mina take place.

72 THE EFFECTS OF PURE AND MICELLAR SOLUTIONS
OF DIFFERENT BILE SALTS ON MUCOSAL MORPHO-
GY IN RAT JEJUNUM IN VIVO. (Eng.) Keeling, J. W.;
mabadusuriya, S. P.; Harries, J. T. (John Radcliffe
sp., Headington, Oxford, England). *J. Pathol.*
8(3):157-163; 1976.

e effects of pure and micellar solutions of dif-
rent bile salts on mucosal morphology were inves-
gated in jejunum from Wistar rats, using a closed-
op technique. The effects of an anionic dihydroxy
eroid antibiotic, fusidic acid, were also studied.
cosal changes were assessed by light microscopical
pearances, and were quantified by determining
rface to volume ratios. The unconjugated dihydroxy
le salts, chenodeoxycholate and deoxycholate (DC),
oduced similar and gross structural changes at
ncentrations of 2.5-5 mM, as judged by mucosal
pearances, but not at 1 mM. The unconjugated tri-
droxy bile salt cholate and a variety of di- and trihydroxy conjugated salts produced no changes at concentrations of 5-20 mM. Fusidate (5 mM) produced changes similar to 5 mM DC. Compared with control values, DC (1, 2.5, and 5 mM) and fusidate (5 mM) produced highly significant ($p<0.001$) reductions in surface to volume ratios. DC-induced damage was completely abolished by mixed micellar solutions, whereas pure micellar solutions provided no protection. These results indicate that there is a molecular specificity for bile salt-induced mucosal damage and that the effects of the unconjugated dihydroxy species on mucosal structure depend not only on their intraluminal concentrations, but also on the relative concentrations of conjugated bile salts and lipids present in the lumen.

0773 SCANNING ELECTRON MICROSCOPY OF NORMAL RAT LIVER: THE SURFACE STRUCTURE OF ITS CELLS AND TISSUE COMPONENTS. (Eng.) Grisham, J. W.; Nopanitaya, W.; Compagno, J.; Nagel, A. E. H. (Univ. North Carolina Sch. Med., Chapel Hill, NC 27514). *Am. J. Anat.* 144(3):295-321; 1975.

Scanning electron microscopic (SEM) observations of hepatocellular structure and hepatic tissue organization of Wistar rats are reported. Hepatocytes presented three structurally distinct faces: the intercellular face containing flat surfaces and bile canaliculus, the sinusoidal face, and the connective tissue face that abuts portal tracts and hepatic veins. Hepatic parenchyma were segmented by the regular interdigitation of hepatic veins and portal tracts that ran perpendicularly between hepatic venous "limbs." Portal tract interiors afforded a view of ductal epithelial cells that contained frequent microvilli and occasional cilia. Microvilli were often concentrated in rows along the circumference of the ductal lumen. Hepatic arterial branches possessed relatively thick walls for their small size and longitudinally ridged endothelium that was sparsely studded with short, thick microvilli. Polyhedral and multifaceted hepatocytes, one cell thick, were penetrated by sinusoids (lacunae). Generally, the plates were straight and situated between neighboring portal and hepatic veins. Canaliculi (0.5 µm -1.0 µm in width) possessed microvilli crowded at their margins. Canalicular surfaces facing the cell body were smooth, containing only a few microvilli. Usually the canaliculi were located at the center of the hepatocellular plates, tending to be straight and unbranched. Connections between canaliculi and perisinusoidal spaces were not seen. The sinusoidal surface contained 25-50 microvilli/µm^2 and the endothelium was widely fenestrated by both large (1.0-3.0 µm in diameter) and small (0.1 µm) openings. The sinusoids were round or oval averaging 20-40 µm in diameter. Sinusoidal cells with plump, nonfestrated cytoplasm were suspected to be Kupffer cells. Terminal hepatic veins were usually two or three times the size of the sinusoids draining into them; however, the largest veins did not receive sinusoidal collagen. Portal and hepatic

LIBRARY U. OF I.

canals were lined with a nearly continuous layer of hepatocytes. The hepatic capsule was covered by a continuous layer of serosal cells studded with microvilli. Thus, SEM allows the visualization of surface characteristics and inter-relations of hepatocytes and hepatic plates, sinusoidal endothelial cells and sinusoids, presumed Kupffer cells, vessels, bile ducts, connective tissue, and the capsule of rat liver.

0774 IN VIVO ASSEMBLY OF TIGHT JUNCTIONS IN FETAL RAT LIVER. (Eng.) Montesano, R.; Friend, D. S.; Perrelet, A.; Orci, L. (Institut d'Histologie, Ecole de Medecine, 1211 Geneva, Switzerland). *J. Cell Biol.* 67(2):310-319; 1975.

The mode of formation of the basic detectable unit of the tight junction, the smooth-contoured fibril or ridge, was investigated electron microscopically in glutaraldehyde-fixed, freeze-fractured livers from 14- to 15-gestational day-old rat fetuses. Membrane particles aligned in otherwise poorly particulated areas of the presumptive pericanalicular plasma membrane (A face), frequently forming a discontinuous honeycomb network joining small particle islands. Contigous B-fracture faces contained furrows, rather than rows of pits, distinguishing the linear particle aggregates on the A face as developing tight junctions rather than gap junctions. Short segments of these linear arrays merged with smooth ridges, clearly identifiable as segments of discontinous tight junctions. Mature tight junction became fully identifiable with the continuing confluence of particulate and smooth ridge sections. By 21 days, most of the images of assembly had disappeared, and the structure was that of well-formed bile canaliculi sealed by mature tight junctions. It is concluded that the tight junctions form *de novo* by the aligment and fusion of separate particles into beaded ridges, which, in turn, become confluent and are transformed into continuous smooth ones.

0775 JUNCTIONS BETWEEN SINUSOIDAL ENDOTHELIAL CELLS IN FETAL RAT LIVER. (Eng.) Montesano, R. (Sch. Medicine, Univ. Geneva, 1211 Geneva 4, Switzerland). *Am. J. Anat.* 144(3):387-392; 1975.

A freeze-fracture study of the livers of 14-to 21-day rat fetuses demonstrated unusual patterns of intramembranous particles in regions of contact between sinusoidal endothelial cells. On the A fracture face, these arrays were mostly associated with linear elevations or crests. When the linear crests were lacking, the arrays appeared as parallel arrays of particles on flattened membrane faces. The particles in the arrays were approximately 9-11 nm in diameter and were usually separated by small intervals. These linear arrays may either represent a new type of junction or an abortive form of tight junction.

0776 EXTRACELLULAR CALCIUM AND THE ORGANIZATION OF TIGHT JUNCTIONS IN PANCREATIC ACINAR CELLS. (Eng.) Galli, P.; Brenna, A.; De Camilli, P.; Meldolesi, J. (CNR Center Cytopharmacology, Univ. Milan, 20129 Milan, Italy). *Exp. Cell. Res.* 99(1): 178-183; 1976.

The effect of extracellular calcium on the organization of tight junctions in pancreatic acinar cells was investigated in freeze-fracture studies. Guinea pig pancreas lobules were incubated in one of the following media: complete Krebs-Ringer bicarbonate solution (KRB); Ca^{2+}-free KRB; or Ca^{2+}-free KRB containing 0.5 mM EGTA. In the latter medium, the tight junctions were disarrayed after only 10 min incubation, and then broke up into fasciae occludentes. In lobules incubated for 60-120 min, the fasciae occludentes broke into fragments, which moved laterally in the plane of the plasmalemma and often located around the gap junctions. Interrupting the continuity of tight junctions resulted in the disappearance of different intramembranous particle density between the lateral and luminal regions of the plasmalemma. Similar findings occurred with lobules incubated in a Ca^{2+}-free medium without EGTA, but this disorganization was less marked. These results are consistent with the interpretation of tight junctions as dynamic structures and confirm that tight junctions might play a role in establishing and maintaining the regional differences of the plasmalemma.

0777 IDENTIFICATION OF CELLS WITH PANCREATIC-TYPE AND GUT-TYPE GLUCAGON IMMUNOREACTIVITY IN THE HUMAN COLON. (Eng.) Knudsen, J. B.; Holst, J. J.; Asnoes, S.; Johansen, A. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 83(6):741-743; 1975.

Ten normal human colon biopsy specimens from the anus of 5 young and middle-aged persons and 16 pancreatic specimens from 8 middle-aged patients were examined for the presence of glucagon cells with pancreatic-type and gut-type immunoreactivity. For comparison, pancreatic samples from normal Balb/c mice were also examined. Indirect immunofluorescence staining, indirect immunoperoxidase staining, and specific antisera against porcine glucagon coupled to bovine serum albumin were used to detect the glucagon immunoreactivity. Pancreatic glucagon cells in the islets of Langerhans were equally distinct, whether demonstrated by one or the other immunohistochemical techniques or by antisera in the human or the mouse pancreas. By all techniques, cells showing both types of glucagon immunoreactivity were demonstrated in the human colonic mucosa. On an average, 3.3 cells were found per crypt, mostly in the middle and deeper parts.

0778 CATECHOLAMINE-CONTAINING NERVE FIBRES IN THE HUMAN ABDOMINAL VAGUS. (Eng.) Lundberg, J.; Ahlman, H.; Dahlstrom, A.; Kewenter, J. (Univ. Goteborg, S-413 45 Goteborg, Sweden). *Gastroenterology* 70(3):472-474; 1976.

The presence of adrenergic nerve fibers in the human vagal nerve was investigated in specimens excised from six patients undergoing thoracic or abdominal surgery. The nerves were crushed 30-60 min before excision of a 10-mm segment above and below the crush, and the specimens were freeze-dried and prepared for fluorescent microscopy. The right anterior main trunk (subdiaphragmatic level), taken from one patient undergoing distal esophagectomy, and the anterior nerve of Latarget, taken from five patients undergoing selective vagotomy and pyloroplasty, contained unmyelinated nerve fibers with accumulations of green fluorescent material representing catecholamine. These observations indicate the presence of adrenergic nerve fibers running caudally in the human vagal nerve, similar to findings in other mammals.

0779 DIFFERENTIATION ASSOCIATED CHANGES IN THYMIDYLATE SYNTHETASE AND THYMIDINE KINASE ACTIVITIES IN INTESTINAL CELLS. (Eng.) Peterson, A. M. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021). *Cell Differ.* 5(1):37-43; 1976.

Proliferative and mature intestinal cells of the jejunum and colon of male CFN rats,of human colon, and of the surface cells of human neoplastic colonic lesions were assayed for thymidylate synthetase and thymidine kinase activities. Cells from the proliferative region of rat jejunal mucosa were found to have higher enzyme activities than cells from the nonproliferative region. Thymidylate synthetase activity decreased as cells migrated from base to upper crypt, whereas thymidine kinase activity increased during crypt migration, and then declined as cells migrated onto villi. Thymidine kinase activity also remained elevated longer than thymidylate synthetase during cell migration in colonic mucosa of rat and man. High thymidine kinase:thymidylate synthetase ratios similar to those observed in flat mucosa before cells become fully mature were found in cells removed from expanding human neoplastic lesions. The results support, but do not confirm, the possibility that the enzyme activity profile reflects a specific stage of differentiation of the epithelial cells of the neoplasms.

786 AN ANALYSIS OF THE D-GLUCOSE INFLUX KINETICS OF IN VITRO HAMSTER JEJUNUM, BASED ON ONSIDERATIONS OF THE MASS TRANSFER COEFFICIENT. Eng.) Dugas, M. C.; Ramaswamy, K.; Crane, R. K. Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15213). *iochim. Biophys. Acta* 382(4):576-589; 1975.

he effects of unstirred layers on the apparent glu- ose-influx kinetics of hamster jejunum were studied. he apparent maximum velocity, V, was 12.81, 10.71, .75, 10.17, and 9.33 μmol/cm^2/hr while the apparent ichaelis constant for glucose influx, K_m, was 7.42, .95, 1.87, 0.93, and 0.5 mM, resp., when the rate of shaking the incubation flasks was 40, 80, 120, 160, and 200 cycles/min, resp. Extrapolation of the slope and reciprocal intercept of Lineweaver-Burke plots of the data to infinite shaking rate was mathematically justified to yield the slope and intercept of a Lineweaver-Burke plot uncomplicated by unstirred layers. These extrapolations had a regression coefficient of 1 when plotted as (intercept)$^{-1}$ or slope=$b_0+b_1b-(\text{shake})^2$ where b=2.764 for the slope plot and 6.626 for the (intercept)$^{-1}$ plot. From these values of b_0, K_m, and V were determined as 0.41 and 9.35, resp. These values should represent the true kinetic parameters for glucose influx into this tissue under the experimental conditions em-

LIBRARY U. OF I. URBANA-CHAMPAIGN

ployed. Values of the theoretical flux expected on a basis of unstirred-layer thickness calculated from the relation C_b (for $J = V/2$) $= K_m + 0.5V/K_d$ agreed with the experimental values of J in some instances but the 95% confidence interval of the theoretical and experimental values did not overlap in many instances at low shaking rates and low concentrations of glucose. A factor θ representing the error between the theoretical and experimental values was found to fit the relationship ln(theoretical J) = $-3.8 + 5.77\ (1/\theta)$ with a regression coefficient of 0.98 and was proposed to be due to one or more of the following parameters: a villus tip to base gradient of transport (influx) activity; a dependence of brush-border influx area on substrate concentration in the bulk incubation media; and an end product inhibition of the overall transport rate. The data indicate that the flux of glucose across the unstirred layer is ordinarily the rate-limiting step in the *trans*-brush border transport of this sugar by hamster jejunum when less than saturating concentrations of glucose are used. At high shaking rates the contribution of the unstirred layer is reduced.

0787 CIRCADIAN RHYTHMS OF INTESTINAL SUCRASE AND GLUCOSE TRANSPORT: CUED BY TIME OF FEEDING. (Eng.) Stevenson, N. R.; Fierstein, J. S. (Rutgers Medical Sch., Piscataway, NJ 08854). *Am. J. Physiol.* 230(3):731-735; 1976.

Changes in the activity patterns and the daily average levels of activity of sucrase and the absorptive transport system for glucose were studied in male Sprague-Dawley rats subjected to artificial feeding schedules. Under constant illumination, the activities of sucrase and the absorptive transport system for glucose followed circadian rhythms on both ad libitum and controlled feeding regimens. In the ad libitum group, sucrase and transport activities were higher during the early morning and lower during the early evening. In response to controlled feeding at 1400-1800 hr, sucrase activity peaked at 1300 hr and was at a minimum at 0500 hr. Transport activity peaked at 1700 hr and was at a minimum at 0700 hr. When the feeding period was changed to 0200-0600 hr, the rhythms shifted by 12 hr. Restriction of feeding also resulted in an enhanced average daily activity level for both functions over the ad libitum group. It is concluded that the rhythms of these functions result from feeding patterns of previous days.

0788 INFLUENCE OF SPECIFIC DIETARY SUGARS ON THE JEJUNAL MECHANISMS FOR GLUCOSE, GALACTOSE, AND α-METHYL GLUCOSIDE ABSORPTION: EVIDENCE FOR MULTIPLE SUGAR CARRIERS. (Eng.) Debnam, E. S.; Levin, R. J. (Royal Free Hosp. Sch. Medicine, 8 Hunter St., London, WC1 1BP, England). *Gut* 17(2): 92-99; 1976.

The effects of feeding glucose, galactose, and α-methyl glucoside on the kinetics of absorption of these sugars in the jejunum of fasting albino male Sheffield rats were assessed by chemical and electrical methods for characterizing the electrogenic active transfer mechanisms *in vivo*. The parameters of apparent K_m (an index of carrier affinity) and V_{max} (an index of the maximum jejunal transfer capacity) were obtained from the kinetic data to describe quantitatively the active transport mechanisms in rats fed their normal solid diet, in rats deprived of solid food for 3 days, and in rats deprived of solid food but allowed *ad libitum* access to isotonic solutions of glucose, galactose, or α-methyl glucoside for up to 3 days. Feeding the sugars to fasting rats produced complex differential effects on the apparent K_m's and V_{max}'s of the various transport mechanisms. The changes were explained by alterations in the transport mechanisms rather than by nonspecific changes in intestinal morphology or metabolism. The differential effects induced by the feeding sugars support the concept that jejunal enterocytes possess multiple carriers or mechanisms for the absorption of actively transported sugars *in vivo*. The multiple forms of the sugar carriers may be involved in the facultative responses of the enterocytes to changes in the dietary levels of sugar and may be important in understanding the influences of disease and nutritional status on absorption processes in man.

0789 INTESTINAL UPTAKE OF MACROMOLECULES. IV. THE EFFECT OF PANCREATIC DUCT LIGATION ON THE BREAKDOWN OF ANTIGEN AND ANTIGEN-ANTIBODY COMPLEXES ON THE INTESTINAL SURFACE. (Eng.) Walker, W. A.; Wu, M.; Isselbacher, K. J.; Bloch, K. J. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 69(6):1223-1229; 1975.

The possible role of pancreatic enzymes in the degradation of antigens and antigen-antibody complexes on the surface of the small intestine was investigated in adult female Sprague-Dawley rats. Groups of six rats were immunized by i.p. injection of crystalline bovine serum albumin (BSA) labeled with $Na^{125}I$ emulsified in incomplete Freund's adjuvant (IFA). Control rats were injected i.p. with equal volumes of saline and IFA. There was significantly less breakdown of $[^{125}I]$BSA by both jejunal and ileal gut sacs from BSA immunized, pancreatic duct-ligated rats compared with BSA sham-operated controls. Treatment of the immunized, pancreatic duct-ligated rats with pancreatic extracts prior to removal of the gut sacs, led to an increase in the breakdown of $[^{125}I]$BSA by the gut sacs *in vitro*. These findings suggest that pancreatic enzymes adsorbed to the surface of the intestine contribute to the proteolysis of antigens and antigen-antibody complexes at this site.

0790 UPTAKE OF MACROMOLECULES BY ENTEROCYTES ON TRANSPOSED AND ISOLATED PIGLET SMALL INTESTINE. (Eng.) Leary, H. L., Jr.; Lecce, J. G. (Animal Science Dept., North Carolina State Univ., Raleigh, NC 27607). *J. Nutr.* 106(3):419-427; 1976.

The effect of digesta on enterocyte closure (cessation of internalizing of fluorescent protein) as it relates to the position of the enterocyte in the digestive path of the neonatal piglet was studied by either surgically transposing a portion of the ileum to the proximal third of the small intestine or isolating different regions of the small intestine from the direct digestive path. Transposition experiments illustrated that the neonatal piglet possesses a differentiated intestinal epithelium with regard to its capacity to internalize macromolecules; enterocytes on ileum surgically transposed to the proximal intestine continued to internalize fluorescent protein after enterocytes on the proximal intestine on each side of the transposed ileum ceased. Upon isolation from the direct digestive pathway, enterocytes on intestinal segments from the proximal, middle, and distal thirds of the small intestine internalized fluorescent protein longer than comparable enterocytes remaining in the digestive path. It is concluded that digesta accelerates the rate of termination of the differentiated capacity of the neonatal piglet intestinal epithelium to internalize macromolecules.

0791 QUANTITATIVE ASSESSMENT OF THE TRANSMISSION OF LABELLED PROTEIN BY THE PROXIMAL AND DISTAL REGIONS OF THE SMALL INTESTINE OF YOUNG RATS.

(Eng.) Morris, B.; Morris, R. (Dept. Zoology, Univ. Nottingham, Nottingham NG7 2RD, England). *J. Physiol. (Lond.)* 255(3):619-634; 1976.

The amount of labeled protein transmitted from the proximal and distal regions of the small intestine was measured in Wistar rats by determining the rate at which labeled (^{125}I) immunoglobulin G (IgG) left the vascular compartment, the rate of catabolism of labeled IgG, and the distribution of radioactivity in certain abdominal organs. The plasma volume in rats aged 15-16 days was measured by dilution analysis using homologous labeled IgG. A mean plasma volume of 5.53 ml/100 g and a mean blood volume of 8.01 ml/100 g were obtained. After the injection of labeled IgG into the heart, homogenates of various abdominal organs and of the carcass were prepared. Labeled immunoglobulin G left the vascular compartment at a rate of 9-10%/hr over a 3-hr period. About 11% of the labeled IgG was catabolized in 2 hr. These data were used to make quantitative estimates of the amount of intact IgG transmitted from the proximal intestine and from the ileum after the intraintestinal injection of 1,000 μg of labeled IgG. Homogenates of the animals were prepared, and it was estimated that over 40% of the labeled IgG was transmitted as intact protein from the proximal tissue. The results suggest that no intact IgG was transmitted from the ileum, but about 15% of the protein removed from the ileum was recovered in the whole body as degraded fragments precipitable with trichloroacetic acid. These observations are discussed in the context of the transmission of antibodies, and their relevance to the receptor hypothesis is considered.

0792 CHARACTERISTICS OF RAT JEJUNAL TRANSPORT OF TRYPTOPHAN.

(Eng.) Munck, B. G.; Rasmussen, S. N. (Inst. Medical Physiology A, Juliane Maries Vej 28, 2100 Copenhagen O, Denmark). *Biochim. Biophys. Acta* 389(2):261-280; 1975.

The parameters of rat jejunal transport of tryptophan, the interactions between tryptophan and lysine or methionine, and some aspects of the *trans* effects of cellularly accumulated amino acids were studied. The influx of tryptophan across the jejunal brush border ($J_{mc}{}^{Trp}$) could be accounted for by the carrier of α-aminomonocarboxylic acids alone. Tryptophan competed with lysine for the carrier of basic amino acids across the brush border membrane without itself being transported by this carrier. Lysine had neither *cis* nor *trans* effects on $J_{mc}{}^{Trp}$; whereas, intracellular tryptophan was highly inhibitory to $J_{mc}{}^{Lys}$. The intracellular concentration of lysine and of tryptophan, $[Lys]_c$ and $[Trp]_c$, were unaffected by tryptophan and lysine, resp., although the transmural fluxes, from the mucosal side to the serosal side of lysine, ($J_{ms}{}^{Lys}$) and of tryptophan, ($J_m{}^{Trp}$) were inhibited by tryptophan and lysine, resp. The latter effects inhibited interactions at the basolateral membrane. Methionine was a potent *cis* and *trans* inhibitor of $J_{mc}{}^{Trp}$, but stimulated $J_{ms}{}^{Trp}$ and reduced $[Trp]_c$. Methionine caused *trans* acceleration of the influx of lysine across the brush border membrane, $J_{mc}{}^{Lys}$. but had no effect on the influx of galactose, $J_{mc}{}^{Gal}$. Leucine caused *trans* inhibition of $J_{mc}{}^{Leu}$. Tryptophan did not cause *cis* inhibition of $J_{mc}{}^{Gal}$, but was a strong *trans* inhibitor of $J_{mc}{}^{Gal}$. Cellularly accumulated tryptophan appeared to accelerate the eventual decline in transepithelial potential difference and short-circuit current. The results indicate that tryptophan is transported across the brush border membrane by the carrier of neutral amino acids alone, but leaves the cell across the basolateral membrane by a mechanism used by lysine also. They also indicate that leucine, methionine, and probably tryptophan have a *trans* effect on the transport of neutral amino acids across the brush border membrane which may represent decelerating exchange diffusion and that cellulary accumulated tryptophan has a strong and indiscriminate depressive effect on all transport function of rat jejunal epithelium.

0793 MECHANISM OF ACTION OF ASPIRIN ON CANINE GASTRIC MUCOSA.

(Eng.) Kuo, Y. J.; Shanbour, L. L. (Univ. Texas Medical Sch., Houston, TX 77025). *Am. J. Physiol.* 230(3):762-767; 1976.

To determine whether permeability or inhibition of active transport is the primary action resulting from exposure of canine gastric mucosa to aspirin, tissue electrical resistance was measured *in vivo* and ion fluxes were measured *in vitro*. In an *in vivo* chambered canine stomach preparation, exposure of the gastric mucosa to 5, 10, and 20 mM aspirin (pH 3.0) resulted in a decrease in electrical potential difference (PD) and in an increase in resistance (R) within 30 min. *In vitro*, exposure of the mucosal side of the isolated canine gastric mucosa to 5, 10, and 20 mM aspirin (pH 3.0) for 1 hr or of 1 mM aspirin (pH 3.0) for longer than 1 hr resulted in marked permeability changes, i.e., increases in the unidirectional fluxes of Na^+ and Cl^-, as well as inhibition of net ion fluxes. These concentrations of nonionized aspirin (pH 3.0) also reduced the R and PD. However, 1 mM aspirin (pH 3.0) or 20 mM ionized aspirin (pH 7.4) depressed the active transport of ion, in-

LIBRARY U. OF I.

creased R, but did not increase the ionic permeability. Mucosal ATP content was reduced by mucosal instillation of aspirin (pH 3.0). These results demonstrate that the initial action of aspirin, inhibition of ion transport, is followed by an increase in permeability.

0794 EFFECTS OF CHOLECALCIFEROL ON THE TRANSLOCATION OF CALCIUM BY NON-EVERTED CHICK ILEUM IN VITRO.

(Eng.) Holdsworth, E. S.; Jordan, J. E.; Keenan, E. (Dept. Biochemistry, Univ. Tasmania, Hobart, Tasmania 7001, Australia). *Biochem. J.* 152(2):181-190; 1975.

The translocation of Ca^{2+} by white crossbred (Leghorn X Australorp) chick ileum and the effect of pretreatment with cholecalciferol (400 IU) was investigated in an apparatus that allowed perfusion of a noneverted segment of intestine *in vitro*. Krebs-Ringer bicarbonate containing 10 mM glucose, 1 mM Ca^{2+}, and 1 mM P_i was used as a standard physiologic medium and the transport of Ca^{2+} was calculated from the changes in radioactivity of ^{45}Ca. The changes in Ca^{2+} of the perfusion fluids measured by atomic absorption was insignificant, but tissues actually lost Ca^{2+} to the medium during the 30 min of perfusion. Pretreatment with cholecalciferol *in vivo* increased the permeability to Ca^{2+} of the microvillus of the cell in either direction (lumen to cell or cell to lumen). This increased transport can be partially mimicked by 1 mM sodium dodecyl sulfate added *in vitro*. The sign and the magnitude of the electrical potential difference prevailing across the ileum did not influence Ca^{2+} transport. Exit of Ca^{2+} from the mucosal cell was temperature-sensitive, requiring metabolic energy and Na$^+$. Pretreatment with cholecalciferol caused increased movement of Ca^{2+} out of the cell across the basement membranes. This effect was markedly increased by the presence of dicyclohexylcarbodi-imide (0.1 mM) in the perfusion fluid. These observations suggest that cholecalciferol increases Ca^{2+} entry and exit at the mucosal surface and also causes Ca^{2+} to be more available to the pump at the serosal surface.

0795 EFFECT OF DIURETICS ON INTESTINAL TRANSPORT OF ELECTROLYTES, GLUCOSE, AND AMINO ACID.

(Eng.) Huang, K. C.; Dinno, M. A.; Gelbart, D. R. (Univ. Louisville Health Sciences Center, Louisville, KY 40201). *Proc. Soc. Exp. Biol. Med.* 151(4):779-784; 1976.

The effects of ethacrynic acid (EA), furosemide, and amiloride on the electrical properties and ion, glucose, and amino acid transport of the jejunal mucosa of Swiss-Webster albino mice were studied *in vitro*. The membrane was bathed in Krebs-Ringer solution with or without glucose. When EA, furosemide, or amiloride was added to the bathing fluid of both sides, a transient increase followed by a decrease of both potential difference and short circuit current were observed. In glucose-containing bathing medium, EA inhibited both net Na and Cl flux and residual flux; however, EA had little effect on both Na and Cl flux in glucose-free bathing medium. Studies using everted intestinal sac technique showed that EA inhibited both glucose and L-tyrosine across the mucosal membrane against concentration gradients. Furosemide and amiloride were less potent than EA in inhibiting the Na and Cl flux when the bathing solution contained glucose. But they had no effect on glucose and L-tyrosine transport across the intestinal mucosa. Furthermore, they did inhibit Cl flux even in glucose-free bathing medium. It is postulated that all three diuretics act on the brush-border membrane of the intestine. EA probably inhibits the Na-glucose cotransporting system; furosemide and amiloride inhibit the simple diffusion process of Na entry or Cl exit by decreasing the conductance of the membrane.

0796 PATHWAY OF SODIUM MOVING FROM BLOOD TO INTESTINAL LUMEN UNDER INFLUENCE OF OXYPHENISATIN AND DEOXYCHOLATE.

(Eng.) Nell, G.; Forth, W.; Rummel, W.; Wanitschke, R. (Institut fur Pharmakologie und Toxikologie, Universitat des Saarlandes, D-6650 Homburg (Saar), Federal Republic of Germany). *Naunyn-Schmiedebergs Arch. Pharmacol.* 293(1):31-37; 1976.

The pathway of sodium from blood to intestinal lumen was studied in female Wistar rats treated with deoxycholate (D) or oxyphenisatin (O). The transfer of ^{51}CrEDTA and inulin across the rat colonic mucosa *in vivo* was increased by O (3.5×10^{-5} M) and D (3×10^{-3} M). O and D did not change the size of the intra- and extracellular fluid compartments of the mucosa as measured with ^{51}CrEDTA from the blood side. The sodium and potassium content of the mucosal tissue was not altered and the intracellular concentrations of sodium and potassium remained constant. The time course of the ^{22}Na uptake into the mucosal epithelium was not influenced by O and D up to 5 min after i.v. injection. The specific activity of sodium, however, in the luminal fluid increased under the influence of O (twofold) and D (fivefold). The uptake of ^{22}Na into the mucosal tissue after administration of ^{22}Na into the intestinal lumen was not changed in the presence of O and D. It is concluded that the net transport of sodium and water from blood to lumen under the influence of O and D occurs mainly via the intercellular way.

0797 THE EFFECT OF SODIUM TAUROCHOLATE ON THE PERMEABILITY OF ANTRAL AND FUNDIC GASTRIC MUCOSA.

(Eng.) Birkett, D. H.; McColl, I. (Boston City Hosp., 818 Harrison Ave., Boston, MA 02118). *J. Surg. Res.* 20(3):157-161; 1976.

The effect of sodium taurocholate on the permeability of antral and fundic gastric mucosa was studied *in vitro*. A preparation of rabbit antral and fundic gastric mucosae was mounted in an Ussing chamber and perfused with a physiological bicarbonate solution at 37 C. Permeability was measured by the transmucosal flux of [^{14}C]erythritol. Sodium taurocholate (20 mM) at pH 7.4 in the mucosal solution did not increase the flux of erythritol across fundic tissue when compared to controls but did cause a significant fall in tissue resistance. However, sodium taurocholate (20 mM) at pH 7.4 in the mucosal solution of antral tissue increased the flux of erythritol after 30 min when compared with controls, 2.23 and 0.68 pmol/cm^2/sec, resp., and caused a significant fall in tissue resistance. At pH 2.5, sodium taurocholate (2 mM) in the mucosal solution increased the flux of erythritol across fundic tissue when compared with controls, 5.73 and 0.82 pmol/cm^2/sec, resp., and statistically reduced tissue resistance. In antral tissue sodium taurocholate (2 mM) at pH 2.5 increased erythritol flux across antral tissue when compared with controls, 13.97 and 1.38 pmol/cm^2/sec, resp., and statistically reduced tissue resistance. In treated mucosa the slope of the regression of flux against time was significantly greater in antral than fundic tissue, indicating greater antral mucosal permeability. At both high and low pH the increase in physical permeability caused by taurocholate was greater in antral than fundic mucosa. The greater permeability of the antral compared to the fundic tissue suggests that the antrum is more susceptible to injury.

0798 USE OF AN ELEMENTAL DIET IN ANIMALS DURING TREATMENT WITH 5-FLUOROURACIL (NSC-19893). (Eng.) Bounous, G.; Maestracci, D. (Centre Hospitalier Universitaire, Sherbrooke, Quebec, Canada J1H 5N4). *Cancer Treat. Rep.* 60(1):17-22; 1976.

The systemic nutritional effects of 5-fluorouracil (5-FU) enteropathy and its possible mitigation by dietary management were investigated in male Wistar rats. Rats fed a diet containing casein hydrolysate (10% weight/weight, diet 3), instead of whole casein (diet 1) exhibited increased tolerance to nine consecutive daily injections of 15 mg/kg of 5-FU. The relative nutritional efficiency of diet 3 was significantly higher during 5-FU treatment. Serum albumin levels measured after 5-FU treatment dropped by only 2.7% in diet 3 groups and by 13.5% in diet 1 groups. Serum albumin values for rats on the control diet were comparable to those on diet 1. No 5-FU-related mortality was observed in any of the groups. Intestinal brush border enzymes were determined in a group of rats on diet 1. At the end of 5-FU treatment, statistically significant changes were observed: sucrase dropped to 30% of control, and leucylnaphthylamide-hydrolyzing activity dropped to 19% of control. The activity of γ-glutamyltransferase did not change significantly. The authors suggest under these circumstances, a mixture with a prevalence of free amino acids (casein hydrolysate) may be more readily absorbed than a corresponding mixture containing a larger proportion of oligopeptides.

0799 EFFECT OF NON-IONIC DETERGENTS ON THE ABSORPTION OF OLEIC ACID IN THE ANAESTHETISED RAT. (Eng.) Sheltawy, M. J.; Losowsky, M. S. (St. James's Hosp., Leeds L 59, 7TF, U.K.). *Biomedicine* 22(6):468-472; 1975.

The effects of bile salts and of Tween 80 and Pluronic F68 (nonionic detergents) on the absorption and esterification of oleic acid (in presence of monoglyceride) by loops of female Wistar rat intestine were studied *in vivo*. Absorption of oleic acid was highest from 10 mM taurocholate, but was also substantial from the nonionic detergents. Tween 80 acted synergistically with low concentrations of bile salts. Most of the absorbed fatty acid recovered in the intestinal wall was esterified, the proportion found as triglyceride being greater when a nonionic detergent was present. A much smaller proportion of radioactive label left the intestine after absorption from 10 mM taurocholate than from 2 mM taurocholate or from the nonionic detergents. The experiments indicate that in low concentrations Tween 80 and Pluronic F68 may improve the absorption of fatty acids previously impaired due to bile salt deficiency.

0800 TREATMENT WITH GLUCAGON-BINDING ANTIBODIES ALTERS THE INTESTINAL RESPONSE TO STARVATION IN THE RAT. (Eng.) Rudo, N. D.; Lawrence, A. M.; Rosenberg, I. H. (Dept. Medicine, Univ. Chicago, Chicago, IL). *Gastroenterology* 69(6):1265-1268; 1975.

Plasma glucagon levels were determined in diabetic and starved Sprague-Dawley male rats by a double antibody radioimmunoassay. In addition, the effect of treatment with glucagon-binding antibodies in partially starved animals was studied to determine why everted intestinal rings from these animals accumulate nonmetabolizable 1-amino-cyclopentane-5-carboxylic acid (ACPC) at an enhanced rate. When serum glucagon levels were measured in rats 5 days after experimental induction of diabetes with alloxan (150 mg/kg, i.p.) or streptozotocin (65 mg/kg, i.v.), and in rats that were partially starved for 6 days, both groups exhibited increased serum glucagon levels, when compared to controls. Treatment with glucagon-binding antibody (0.5 ml, every 8 hr for 4 days) significantly decreased, towards normal, the ability of intestine from partially starved animals to accumulate ACPC ($p<0.05$). These data suggest that hyperglucagonemia influences the intestine of partially starved rats to augment intestinal transport. The observed changes in intestinal transport function may represent a new population of epithelial cells either changed in number or altered quantitatively by a prolonged exposure to increased serum glucagon levels.

0801 INTERACTIONS OF CATIONIC BILE SALT DERIVATIVES WITH THE ILEAL BILE SALT TRANSPORT SYSTEM. (Eng.) Firpi, A.; Walker, J. T.; Lack, L. (Duke Univ. Medical Center, Durham, NC 27710). *J. Lipid Res.* 16(5):379-385; 1975.

A series of cationic bile salt derivatives (cholamine conjugates) were prepared with one, two, and three α-hydroxyl groups on the steroid moiety and these compounds were examined for active transport across intestinal mucosa in incubations of everted sacs from each of the four quarters of guinea pig small intestine. No such active transport occurred,

LIBRARY U. OF I.

but these sacs did actively transport taurocholate. The compounds inhibited active transport of taurocholate, taurodehydrocholate, and taurochenodeoxycholate. Lithocholylcholamine (one hydroxyl group) was the most effective inhibitor, with 50% inhibition at 0.20 μmol/ml. Cholylcholamine was the least effective inhibitor. The ability of deoxycholylicholamine to inhibit the transport of taurodehydrocholycholamine was approximately twice (0.17 μmol/ml) the potency observed when taurocholate was used as the test substrate. *In vivo* perfusion experiments demonstrated that deoxycholylcholamine (0.15 mg/ml) reversibly inhibited the transport of sodium taurodehydrocholate (0.15 mg/ml) across the guinea pig ileal mucosa. When the concentration of deoxycholylcholamine was raised to 0.30 mg/ml, there was an initial depression in the rate of taurodehydrocholate transport followed by a subsequent increase above the control level, which was interpreted as reflecting an alteration of membrane permeability. Inhibition of taurocholate absorption was less pronounced than that of taurodehydrocholate. The trihydroxy compound was a less effective inhibitor that either of the two dihydroxy compounds tested. In a liver perfusion experiment, 98% of the infused taurodehydrocholate was recovered, and this was not affected by the simultaneous infusion of an equal concentration of deoxycholylcholamine. *In vivo* absorption of glucose by chenodeoxycholylcholamine (0.16 mg/ml) in four experiments was only 10% under conditions that produced approximately 50% inhibition of taurodehydrocholate uptake. The results were consistent with previous structure-activity studies of the active ileal bile salt transport system.

0813 INTESTINAL PROPULSION IN THE DOG: ITS RELATION TO FOOD INTAKE AND THE MIGRATORY MYOELECTRIC COMPLEX. (Eng.) Summers, R. W.; Helm, J.; Christensen, J. (Univ. Hosp., Iowa City, IA 52242). *Gastroenterology* 70(5):753-758; 1976.

Electrical events and flow were studied *in vivo* in the small intestine of six dogs. The transit of a small radioactive bolus injected into the jejunum was monitored by counting from a Biebl loop. After feeding (2-10 hr), the bolus propulsion rate varied within a narrow range. When food and water were withheld over 12 hr, transit of the bolus became highly variable. The variability increased at about the same time as the onset of the migratory myoelectric complex associated with fasting. Electrical recordings from the intestinal muscle demonstrated bolus propulsion into the loop before the band of intense spike potentials, which traveled along the small intestine in the fasted state. The bolus was cleared from the loop when the spike potentials reached this segment. Variability of transit after prolonged fasting can be explained by variability in the rate of migration of the phase of intense spike potentials, and by the timing of the injection of the bolus in relation to the component phases of the electrical complex. Flow is highly dependent upon the electrical activity and the resulting contraction patterns of the small intestine, which are themselves dependent upon feeding.

0814 SOME DIFFERENCES IN CONTRACTILE RESPONSES OF ISOLATED LONGITUDINAL AND CIRCULAR MUSCLE FROM THE GUINEA-PIG STOMACH. (Eng.) Kuriyama, H.; Mishima, K.; Suzuki, H. (Dept. Physiology, Kyushu Univ., Fukuoka 812, Japan). *J. Physiol.* 251(2):317-331; 1975.

The mechanical and electrical properties of the longitudinal (fundus and corpus) and circular (antrum) muscle fibers of the guinea pig stomach were investigated. In the longitudinal but not in the circular muscle, isotonic K Krebs (sodium replaced by potassium) and Na-free (sucrose) Krebs solutions produced a contracture with a tonic component. The different mechanical responses were not accompanied by different membrane responses. Verapamil abolished both phasic and tonic components of K-induced contracture. During the tonic response of the K-induced contracture, repolarization of the membrane by current pulses relaxed the tissue; after cessation of the current pulse, rebound contracture occurred. In the circular muscle, the Q_{10} value for the rate of relaxation induced by inward current pulse was 3.1 and for the development of rebound contracture was 2.4. After immersion in Ca-free isotonic K Krebs solution, application of Ca produced a large contracture in the longitudinal muscle, but contracture in the circular muscle was small or absent. However, the amplitude of subsequent carbachol-induced contracture in the above solution was enlarged in proportion to the durations of Ca treatment in both tissues. Direct tetanic electrical stimulation produced tension in both tissues. With low frequency of stimulation (0.1 Hz), a positive staircase was observed in the circular but not in the longitudinal muscle. It is concluded that topical differences of the motility in the stomach may be due not only to the activity of nervous elements, but also to differences in the properties of the muscle fibers themselves.

0815 MEASUREMENT OF THE MEAN TRANSIT TIME OF DIETARY RESIDUE THROUGH THE HUMAN GUT. (Eng.) Cummings, J. H.; Jenkins, D. J. A.; Wiggins, H. S. (Dunn Nutrition Lab., Milton Rd., Cambridge, U.K.). *Gut* 17(3):210-218; 1976.

The mean transit time (MTT) of digesta through the human gut was measured using a single dose technique. In addition, a constant amount of marker (radio-opaque pellets) was given to six subjects on normal unrestricted diets and five subjects on controlled diets over a 4- or 6-week period, resp., and the number of markers recovered in the stools was measured. The MTT measured by this method (MTT-C) was compared with MTT measured by giving single doses of similar markers to the same subjects (MTT-S) and with the 80% transit time (80% TT). Mean values on three dietary regimes for the MTT-C (54.2 hr) and MTT-S (54.2 hr) were lower than that for 80% TT (63.1 hr). The average MTT-C in a group of six healthy young men on unrestricted diets was 2.3 days (range 0.7-4.0). When additional dietary fiber was added to a standard diet, the average MTT-C fell (in all of five subjects) from 2.4 to 1.6 days. The results of the single dose technique suggest that the MTT-S is a more accurate and reproducible method than the 80% TT, and that it correlated better with the MTT-C than does the 80% TT. However, a continuous record of MTT-C demonstrated wide variations in transit time from week to week by this method, even on controlled diets.

0816 TRANSIT THROUGH THE GUT MEASURED BY ANALYSIS OF A SINGLE STOOL. (Eng.) Cummings, J. H.; Wiggins, H. S. (Dunn Nutrition Lab., Milton Rd., Cambridge, U.K.). *Gut* 17(3): 219-223; 1976.

A single-time stool collection and analysis method for measuring transit time through the gut is described. The subject is given 20 radio-opaque markers on each of 3 consecutive days with breakfast using a different but comparable marker on each day. The first stool passed after rising on the fourth day is collected and its marker content analyzed. The method was validated in 15 healthy male subjects by comparing it on 36 occasions with mean transit time measured by a continuous marker technique (MTT-C). In 35 of these studies, transit measured from a single stool (SST) and MTT-C were significantly correlated ($p<0.001$). In one study, the designated stool contained none of the SST markers. An alternative way of validating the SST method is described by comparing it with the average of the three mean transit times from three separate doses of marker (MTT-S). The average MTT-S agreed very closely with MTT-C in 36 studies ($p<0.001$) and proved a satisfactory alternative

LIBRARY U. OF I.

method for validating transit techniques. In a total of 66 studies in 22 subjects the average MTT-S correlated significantly with SST ($p<0.001$). The SST method of measuring transit is accurate over 1-4 days and should be useful for epidemiological studies and as a hospital outpatient procedure.

0817 STOCHASTIC MODEL OF CONTRACTIONS AT A POINT IN THE DUODENUM.

(Eng.) Singerman, R. B. J.; Macagno, E. O.; Glover, J. R.; Christensen, J. (Dept. Internal Medicine, Iowa Inst. Hydraulic Res., Iowa City, IA 52242). *Am. J. Physiol.* 229(3):613-617; 1975.

Contractions at one point in the human duodenum were studied as a time series. Manometric records were made over long time periods from the duodenum in fed human subjects. A 5-sec grid was superimposed on the time axis of the records. Each 5-sec interval was treated as a slow-wave cycle within which either a contraction or a no-contraction could occur. Trends occurred in the resulting series of alternating runs of contractions and no-contractions, indicating possible temporal dependence. A Markov-type model that assumed a probability of contraction dependent on the three previous slow wave cycles was used to try to generate data similar to the real data. The frequency distributions obtained from the real and generated data were compared using Chi-square goodness-of-fit tests and found to be statistically similar. The correlations in time found for the contractions might be due to a time dependency in the controls for contraction over four successive slow-wave periods, 20 sec in humans.

0818 INTRALUMINAL PRESSURES DURING PERFUSION OF THE HUMAN COLON IN SITU.

(Eng.) Chauve, A.; Devroede, G.; Bastin, E. (Centre Hospitalier Universitaire, Sherbrooke, Quebec, Canada). *Gastroenterology* 70(3):336-340; 1976.

Transintestinal intubation was used to investigate and analyze pressure recordings in the right, transverse, and left colon in nine healthy men. Isotonic saline was infused into the cecum at various flow rates from 10-30 ml/min. During colonic perfusions, pressure waves were simple and distorted only by respiratory artifacts. Their amplitude was large (10-44 cm H_2O), of long duration (8-68 sec), and of low frequency (0.2-1.8 wave/min). Wave frequency was very stable, with stability uninfluenced by the site of recording and the rate of perfusion. A pressure wave in the right colon was always followed within 3 sec by a wave in the transverse and left colon. The frequency and amplitude of the waves increased in all subjects and at all rates of perfusion from right to left colon ($p<0.001$). The wave frequency increased with the perfusion flow rate ($p<0.001$). The relationship between the perfusion flow rate and the wave amplitude was curvilinear ($p<0.01$). It is concluded that in the human colon perfused *in situ*, there is a gradient of motility preventing aboral propulsion. This study suggests that during perfusion, liquids are trapped in the right colon. Water and electrolyte transport data obtained from whole colon perfusion may reflect events occurring in the proximal part of the large bowel.

0819 MANOMETRIC STUDIES OF THE HUMAN PYLORUS.

(Eng.) Kaye, M. D.; Mehta, S. J.; Showalter, J. P. (Univ. Vermont Coll. Medicine, C-321, Given Medical Building, Burlington, VT 05401). *Gastroenterology* 70(4):477-480; 1976.

The gastroduodenal junction was studied manometrically by means of simultaneous measurements of pressure and potential difference between skin and mucosa to determine whether this region is a zone of tonically elevated pressure. An accurate and circumferentially sensitive miniature transducer assembly failed to reveal a zone of elevated pressure at the pyloric sphincter of any of eight fasting normal subjects. Additional studies were performed in 10 other subjects using a six-lumen perfused catheter system in which three of the pressure-transmitting catheters had circu ferentially arranged openings at the same axial level. Measurements of pressure and potential difference were obtained basally during intraduodenal infusion of 0.1 N of hydrochloric acid and after intraduodenal instillation of 30 ml of olive oil. Tonic elevation in pressure was recorded simultaneously by all three leads at the gastroduodenal junction in only one subject. Thus, the normal human pylorus was not demonstrated to be a high pressure zone.

0820 LARGE BOWEL MYOELECTRICAL ACTIVITY IN MAN.

(Eng.) Taylor, I.; Duthie, H. L.; Smallwood, R.; Linkens, D. (Dept. Surgery, Univ. Sheffield Sheffield, England). *Gut* 16(10):808-814; 1975.

The myoelectrical activity of the colon and rectum was studied in 108 subjects (with no known pathology in this area), using three types of electrodes--intra luminal, serosal, and cutaneous. Two frequency bands of slow waves were found around the colon. The lower frequency band displayed a similar frequency at all levels of the large bowel when present with no apparent gradient of activity. The higher frequency band varied along the bowel, and was observed more often than the slower. There was little change in frequenc from the right colon along the transverse, but a defi ite gradient existed from the sigmoid down into the rectum. Regular sequences of pressure waves in all regions occurred, corresponding to the slow wave frequency. The observed gradient in slow wave frequency may be related to differences in transit on different sides of the colon.

0821 RELATIONSHIP OF SERUM GASTRIN RESPONSE TO LOWER OESOPHAGEAL SPHINCTER PRESSURE.

(Eng.) Dent, J.; Hansky, J. (Prince Henry's Hosp., Melbourne, Victoria, Australia). *Gut* 17(2):144-146; 1976.

The role of gastrin in controlling lower esophageal sphincter pressure (LESP) was examined by measurement of LESP and serum gastrin response to a test protein solution and a control isosmotic saline solution in 19 healthy volunteers. LESP was measured by constant perfusion manometry in 14 men and 5 women (mean age, 21 yr). Both solutions were associated with significant ($p < 0.005$) rise in LESP, but serum gastrin rose significantly ($p = 0.05$) only after the protein solution. The rise in serum gastrin after the protein solution preceded the rise in LESP by 30 min. These results suggest that the lower esophageal sphincter response to feeding may be independent of protein and is unrelated to gastrin release.

0822 POST PRANDIAL CHANGES IN COLONIC MOTILITY RELATED TO SERUM GASTRIN LEVELS. (Eng.)

Kirwan, W. O.; Smith, A. N. (Western General Hosp., Edinburgh, Scotland). *Scand. J. Gastroenterol.* 11 (2):145-149; 1976.

The correlation of colonic motility response to food and post prandial rise in serum gastrin was examined in 16 subjects. Sigmoid colonic motility was recorded during a basal half hour and for 90 min following the ingestion of a protein meal. Both serum gastrin response and colonic motor activity curves were biphasic. The serum gastrin response occurred 5 min after the motility response began, and it climbed steeply and linearly to 80% above basal at 20 min. This elevation was maintained for 35 min and then fell to 65% at 50 min; a secondary rise, to 92%, was reached at 90 min. Motility was already 30% above basal by the beginning of the gastrin response. The motility index rose in the next 5 min until it was 85% above basal. It then fell gradually to its lowest point (15% above basal at 50 min), but later climbed to 60% above basal at 90 min. The frequency response showed the earliest change, and it may be neurogenic since it preceded the gastrin rise. This response was later "extinguished" and was replaced by waves of increasing amplitude; the sustained nature of this response was closer to the gastrin response.

0823 INTERACTION OF GASTRIN I, SECRETIN, AND CHOLECYSTOKININ ON GALLBLADDER SMOOTH MUSCLE.

(Eng.) Ryan, J.; Cohen, S. (Temple Univ. Sch. Medicine, Philadelphia, PA 19140). *Am. J. Physiol.* 230(3):553-556; 1976.

Experiments were undertaken to define the action of gastrin and secretin on isolated gallbladder smooth uscle strips and to determine whether gastrin or ecretin interacts with cholecystokinin (CCK) in regulating gallbladder motor function. Both CCK and he octapeptide of CCK (CCK-OP) stimulated gallbladder ontraction *in vitro*, with CCK-OP (25 ng/ml) being ore potent. Gastrin I, (1.0-100 ng/ml) had no effect n gallbladder contractility. Secretin (3.0-00 ng/ml) alone also showed no effect on gallbladder mooth muscle, but at 150 ng/ml in combination with CK-OP, it produced a noncompetitive type of inhibiion. Michaelis-Menten kinetics showed the calculated aximum response of the secretin plus CCK-OP interacion to be less than with CCK-OP alone. There was no hange in the dose required to achieve half-maximal esponse. These studies indicate that: CCK-OP as a greater effect on gallbladder contractility than CCK; gastrin I has no effect on gallbladder muscle tone; and secretin acts as a noncompetitive antagonist of CCK-OP. These findings suggest that gallbladder motor function may be determined, in part, by the interaction of secretin and CCK rather than solely in response to CCK.

0824 EFFECT OF DOPAMINE ON THE ESOPHAGEAL SMOOTH MUSCLE IN VIVO. (Eng.)

Rattan, S.; Goyal, R. K. (Southwestern Medical Sch., 5323 Harry Hines Blvd., Dallas, TX 75235). *Gastroenterology* 70(3): 377-381; 1976.

Experiments were conducted to determine the site of action of dopamine, the nature of the receptors that mediate the effect of dopamine, and the effect of dopamine antagonism on the esophageal response to vagal stimulation in the opossum. The i.v. administration of dopamine to 21 animals caused a dose-dependent reduction in the lower esophageal sphincter pressure and contractions in the lowermost part of the body of the esophagus. A dose of 5 µg/kg produced maximal response. The onset of contractions in the body occurred around 20 sec after the onset of the sphincter response. The effect of dopamine was different from isoproterenol (2.5 µg/kg), which caused no contractions in the body and caused reduction in sphincter pressure, and from phenylephrine (50 µg/kg), which also caused no contractions in the body but caused contraction of the sphincter. Moreover, the effect of 5 µg/kg of dopamine was blocked by haloperidol (3 mg/kg) but not by phentolamine (1 mg/kg), propranolol (1 mg/kg), bilateral cervical vagotomy, or tetrodotoxin (10-20 µg). These studies suggest the presence of selective dopamine receptors that mediate contraction of the esophageal body and relaxation of the sphincter muscle. Since vagal stimulation also causes contraction in the body and relaxation of the sphincter, it is possible that vagal effect on the esophagus is mediated by dopamine receptors. However, haloperidol did not block the effect of electrical stimulation of vagus nerve on body of the esophagus or the lower esophageal sphincter.

0825 GASTRODUODENAL MOTOR RESPONSE TO NATURAL MOTILIN AND SYNTHETIC POSITION 13-SUBSTITUTED MOTILIN ANALOGUES: A COMPARATIVE IN VITRO STUDY. (Eng.)

Strunz, U.; Domschke, W.; Domschke, S.; Mitznegg, P.; Wunsch, E.; Jaeger, E.; Demling, L. (Dept. Medicine and Pharmacology, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Scand. J. Gastroenterol.* 11(2):199-203; 1976.

Motor effects of graded concentrations of pure natural porcine motilin (13-Met-M) and synthetic motilin analogues, the methionine in position 13 substituted with either norleucine (13-Nle-M) or leucine (13-Leu-M), on the rabbit, guinea-pig, rat, and human gastrointestinal smooth muscle were examined *in vitro*. Congruent species specificity of the motor activity of the motilins studied was demonstrated; muscle strips from rabbit and man were highly sensitive, whereas guinea-pig and rat preparations were refractory to the polypeptides. In rabbit duodenal muscle and fundic muscle of the hu-

LIBRARY U. OF I.

man stomach, graded concentrations of 13-Met-M, 13-Nle-M, and 13-Leu-M, resp., produced graded increases in the contractile responses. The concentration-response curves were superimposable. Calculated maximal contractile responses (CMR's) and polypeptide doses for one-half maximal responses (D_{50} values) were not significantly different between the three motilins. Pharmacological analysis revealed that the motor effects of 13-Met-M, 13-Nle-M, and 13-Leu-M are not uniformly mediated via nervous pathways. Neither blockage of axonal conduction by tetrodotoxin nor anticholinergic action by atropine exerted any detectable influence. The data suggest that in man and rabbit natural porcine motilin and its synthetic position 13-substituted analogues, 13-Nle-M and 13-Leu-M, are of equal efficacy for gastroduodenal motor activity. In addition, it is concluded that position 13 of the amino acid sequence of motilin (22-residue chain) is not pertinent to the active site of the molecule.

0826 EFFECTS OF RICINOLEIC AND OLEIC ACIDS ON THE DIGESTIVE CONTRACTILE ACTIVITY OF THE CANINE SMALL AND LARGE BOWEL. (Eng.) Stewart, J. J.; Bass, P. (Center Health Sciences, Univ. Wisconsin, Madison, WI 53706). *Gastroenterology* 70(3): 371-376; 1976.

Oleic and ricinoleic acids or their *trans* isomers (elaidic and ricinelaidic acids) were administered intraduodenally in four dogs and evaluated for their effects on the digestive motor activity of the small and large bowel. The animals were implanted with duodenal cannulas and extraluminal strain gage transducers along the circular axis of the proximal and mid-jejunum, terminal ileum, and proximal colon. After feeding 200 g of canned dog food to induce contractile activity, 500 mg of the sodium salt of each fatty acid dissolved in 30 ml of isotonic saline was introduced into the duodenum as a single bolus infusion, and recordings were made for a 1-hr period. A 30-ml volume of saline served as control. Administration of each *cis* fatty acid produced an initial stimulation in jejunal areas of about a 2-min duration followed by a poststimulatory inhibition. Both the initial stimulation and poststimulatory inhibition were greater for ricinoleic acid than for oleic acid. Minimal or no effects were produced in ileal or colonic areas. In contrast, the *trans* isomers produced little or no effect on either the small or large bowel. Digestive contractile pattern alterations produced by p.o. administration of 10 ml of oleic, ricinoleic acid, or their respective triglycerides were also tested. Triolein had no effect. Ricinoleic acid and castor oil produced a brief initial stimulation followed by prolonged inhibition of small bowel motor activity. Digestive motor patterns returned to control approximately 45 min after oleic acid. There was no indication at any time of an initiation of continuous contractile activity after ricinoleic acid or castor oil that could justify the use of the terms "irritant" or "stimulant" to describe their actions.

0827 MANOMETRIC STUDIES ON THE HUMAN PYLORIC SPHINCTER: EFFECT OF CIGARETTE SMOKING, METOCLOPRAMIDE, AND ATROPINE. (Eng.) Valenzuela, J. E.; Defilippi, C.; Csendes, A. (Univ. Chile, Sch. Medicine, Hospital J. J. Aguirre, Santiago, Chile). *Gastroenterology* 70(4):481-483; 1976.

The effects of cigarette smoking, atropine, and metoclopramide on pyloric sphincter pressure were examined in 7, 5, and 14 subjects, resp. Pyloric sphincter pressure was assessed with water-perfused polyvinyl tubes. Smoking one cigarette significantly decreased the basal pyloric pressure from 10.2 ± 1.2 to 7.9 ± 1.1 mm Hg. Ten milligrams of metoclopramide as an i.v. bolus increased the pyloric pressure in six normal subjects and in four patients with gastric ulcer with low basal pressure. Duodenal acidification with 0.1 N HCl significantly increased pyloric pressure. Atropine (15 μg/kg, s.c.) prevented the rise of pyloric pressure in response to acid infusion into the duodenum in all subjects. The results suggest that smoking-induced decrease in pyloric sphincter pressure may contribute to duodenogastric reflux (a possible etiologic factor of gastric ulcers), and that metoclopramide may be effective in gastric ulcer therapy by restoring pyloric pressure and decreasing duodenogastric reflux.

0828 GASTRIC EMPTYING AND SMALL INTESTINAL MUCOSAL INJURY IN RATS. (Eng.) Kent, T. H.; Cannon, B.; Reynolds, J.; Osborne, J. W. (Univ. Iowa Coll. Medicine, Iowa City, IA 52242). *Gastroenterology* 69(6):1246-1253; 1975.

The degree of small intestinal villus injury was related to the degree and mechanism of gastric retention in male Sprague-Dawley rats using an *in vivo* model for inducing injury by perfusion of mid-small intestine with various agents. Potentially injurious solutions 0.1, 0.05, and 0.025 N HCl and NaOH; 0.26 and 0.13 g/30 ml FeSO4; and 0.32, 0.16, 0.08, and 0.04 g/30 ml AgNO3 were infused at 0.5 ml/min for 1 hr. Two hours after perfusion, gastric emptying and small intestinal transit were measured by examining the gastrointestinal distribution of a nonabsorbable radioisotope (50μCi ^{51}Cr/0.5 ml) that had been placed in the stomach for 1 hr. There was a strong association between the degree of villus injury produced by various concentrations of the injurious agents and the degree of gastric retention. Necrosis of villus tips as produced by AgNO3 was sufficient to cause marked gastric retention. Injury to the small intestinal mucosa of one parabiotic rat did not produce gastric retention in the partner. It is concluded that injury to small intestinal villi is sufficient to induce gastric retention and that the effect is most likely nerve-mediated.

SECRETION AND METABOLISM

Stomach

0847 IDENTIFICATION OF GLUCAGON-PRODUCING CELLS (A CELLS) IN DOG GASTRIC MUCOSA. (Eng.) Baetens, D.; Rufener, C.; Srikant, B. C.; Dobbs, R.; Unger, R.; Orci, L. (Univ. Geneva Medical Sch., Geneva, Switzerland). *J. Cell Biol.* 69(2):455-464; 1976.

Immunocytochemical studies using a specific antiglucagon serum were undertaken in gastrointestinal mucosa from 12 dogs to determine whether gastric cells resembling pancreatic A cells are the source of gastric glucagon. Glucagon-containing cells situated exclusively in the oxyntic glandular gastric mucosa were found. Electron microscope examination of the mucosa demonstrated endocrine cells containing secretory granules with a round dense core surrounded by a clear halo, indistinguishable from secretory granules of pancreatic A cells. Like the alpha granules of pancreatic A cells, the granules of these gastric endocrine cells exhibited a peripheral distribution of silver grains after Grimelius silver staining. Moreover, the granules of these cells were found to be specifically labeled with reaction product, using the peroxidase immunocytochemical technique at the ultrastructural level. Accordingly, these cells were named gastric A cells. These data suggest that the gastric oxyntic mucosa contains cells that are cytologically, cytochemically, and immunocytochemically indistinguishable from pancreatic A cells. It is believed that gastric A cells are responsible for the secretion of the gastric glucagon.

0848 THE ROLE OF THE ANTRUM IN DETERMINING THE ACID SECRETORY RESPONSE TO MEALS OF DIFFERENT CONSISTENCY. (Eng.) Hunt, D. R.; Forrest, A. P. M. (St. George Hosp., Kogarah, 2217 NSW, Australia). *Gut* 16(10):774-776; 1975.

The secretory response to meat in homogenized and minced forms was assessed in three dogs with denervated Heidenhain pouches, before and after antral denervation. The acid output from the pouch was measured every 15 min for 4 hr after feeding. The acid output after feeding with homogenized meat exceeded that for minced meat to a significant degree in each dog. Antral denervation reduced the acid response to both meals in two of the dogs, but for all three, the reduction in the mean was significant. Titration showed that when particle size is reduced, the buffering capacity is increased. The results indicate the need for reviewing the effects of food preparation on acid secretion in man.

0849 CHOLINERGIC RELEASE OF GASTRIN BY FEEDING IN CATS. (Eng.) Svensson, S.-O.; Emas, S.; Dorner, M.; Kaess, H. (Karolinska Hosp., Stockholm, Sweden). *Gastroenterology* 70(5):742-746; 1976.

The effect of atropine on acid secretion and serum gastrin level after feeding was studied in eight cats with denervated fundic pouches (Heidenhain pouch, HP). Serum gastrin concentration was measured by radioimmunoassay. In the control experiments, the mean peak acid response occurred 45 min after feeding and the mean peak gastrin concentration 15 min after feeding. After the first postprandial hour, acid secretion declined but the gastrin level remained elevated. Atropine (0.1 mg/kg, i.v.), 5 min before feeding, depressed both acid secretion and the increase in serum gastrin concentration during the first postprandial hour. In both the control and atropine experiments, acid secretion and serum gastrin level were correlated significantly during the first postprandial hour, but no correlation was found later in the experiments. The reduction by atropine of the acid and serum gastrin responses varied among the cats but was correlated significantly. A cholinergic mechanism is implicated in the release of gastrin by feeding in cats during the first postprandial hour. Atropine partly reduces the HP acid response to feeding by depressing the release of gastrin.

0850 VARIATION IN SERUM GASTRIN CONCENTRATION AND HEIDENHAIN POUCH ACID SECRETION DURING FEEDING IN DOGS. (Eng.) Brandsborg, O.; Bone, J.; Brandsborg, M.; Amdrup, E. (Kommunehospitalet, Aarhus Univ., Aarhus, Denmark). *Chir. Gastroenterol.* 9(1):29-36; 1975.

A comparison is made between variations in immunoreactive serum gastrin and Heidenhain pouch secretion during food stimulation in six mongrel dogs. The dogs were prepared with a vagally denervated pouch (HP) and, after 4 weeks of stabilization, were fasted for 18 hr before each experiment. The dogs were given 200 g of standard dog food and blood was taken from a permanent needle inserted into a peripheral vein 30 min before to 5 hr after the meal. Gastrin was measured by radioimmunoassay and the HP secretion collected every 30 min for 5 hr after the test meal. Maximum gastrin concentration occurred 5-15 min after feeding and then fell rapidly, reaching basal levels 3 hr later. No significant acid secretion appeared in 30 min after feeding. Then pouch secretion increased, with maximum levels reached 60-90 min after feeding. Basal levels occurred 5 hr after feeding. A considerable delay between maximum serum gastrin concentration and Heidenhain pouch acid secretion was demonstrated, suggesting that Heidenhain pouch function may be caused by several humoral influences on the parietal cells.

0851 EFFECT OF HYPOPHYSECTOMY AND GROWTH HORMONE ON SERUM AND ANTRAL GASTRIN LEVELS IN THE RAT.

(Eng.) Enochs, M. R.; Johnson, L. R. (Univ. Texas Medical Sch., P.O. Box 20708, 6400 W. Cullen St., Houston, TX 77025). *Gastroenterology* 70(5): 727-732; 1976.

The effects of hypophysectomy and subsequent replacement therapy with growth hormone on serum and antral gastrin levels were investigated in both fasted and nonfasted pair-fed Sprague-Dawley rats. Hypophysectomy caused a 57% decrease in serum and 47% decrease in antral gastrin content in 18-hr fasted animals. In nonfasted animals, hypophysectomy resulted in a 42% fall in serum gastrin and a 76% fall in antral gastrin. Animals were given injections of growth hormone over a 10-day period, then fasted 16-18 hr before being killed. Doses of 100-200 μg/100 g of body weight were ineffective, but a dose of 500 μg/100 g completely restored serum gastrin levels to intact control values. In nonfasted rats this same dose raised serum gastrin to intact levels and increased antral gastrin significantly over hypophysectomized levels but did not increase it to contol values. When given to pair-fed intact animals, growth hormone caused slight but not significant elevations in serum and antral gastrin. The effect of growth hormone on gastrin secretion and/or synthesis may be a significant physiologic factor in the regulation of normal gastrointestinal function and growth.

0852 JEJUNAL INHIBITION OF PENTAGASTRIN-INDUCED GASTRIC ACID SECRETION IN MAN AND HEIDENHAIN POUCH DOGS.

(Eng.) Christiansen, J.; Holst, J. J.; Rokkjaer, M. (Malmtoften 3, DK-2830 Virum, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(2):219-224; 1976.

The effect of intrajejunal administration of hypertonic glucose and saline and of fat on pentagastrin-induced gastric acid secretion in nine healthy human subjects (five men and four women, aged 20-28 yr) and three mongrel dogs is reported. In human studies, an overnight fast was followed by the infusion of a marker substance (^{51}Cr-EDTA, flow 30 ml/hr) to assay recovery. Four of the subjects were controls and infused intrajejunally with physiologic saline. Five other subjects were studied three times on different days. Pentagastrin, 0.5 μg/kg/hr, was administered for 3 hr as a continuous i.v. infusion. When a secretory plateau was attained, 100 ml of 50% glucose, 100 ml of 9.3% saline, or 100 ml of fat emulgation was infused over a 5-min period. In the control group, 100 ml of physiologic saline was infused. In the dog studies, a denervated fundic pouch provided with an abdominal cannula was prepared. Pentagastrin was administered i.v., 1 μg/kg/hr, for 30 min. Following this, 50 ml of 50% glucose solution or 9.3% saline was infused through the cannula for 5 min, and stomach secretions were collected. In the human control study, the physiologic saline did not affect gastric acid secretion. In contrast, the other three solutions (hypertonic saline and glucose and fat) produced a significant decrease in acid output, volume secretion, and acidity. The magnitude was the same irrespective of intrajejunal infusion. In the dog studies, glucose infusion produced an equal inhibition of pentagastrin-induced secretion from the pouch and main stomach, while the 9.3% saline produced little or no effect. The results demonstrate the existence of potent jejunal inhibitors of gastric secretion that may operate independently of vagal innervation.

0853 COMPARISON OF METHYLATED PROSTAGLANDIN E_2 ANALOGUES GIVEN ORALLY IN THE INHIBITION OF GASTRIC RESPONSES TO PENTAGASTRIN AND PEPTONE MEAL IN MAN.

(Eng.) Konturek, S. J.; Kwiecien, N.; Swierczek, J.; Oleksy, J.; Sito, E.; Robert, A. (Inst. Physiology, Grzegorzecka 16, 31-531 Krakow, Poland). *Gastroenterology* 70(5):683-687; 1976.

The effects on gastric secretion of three methyl analogues of prostaglandin (PG)E_2, 15(R)-15-methyl PGE_2 methyl ester, 15(S)-15-methyl PGE_2 methyl ester, and 16,16-dimethyl PGE_2 were studied in random, double blind tests in 32 healthy men. Secretion was measured for 30 min, and a PG analogue (1.25-2.5 μg/kg) or a placebo was administered. Gastric secretion was then stimulated either by an i.v. infusion of pentagastrin (2 μg/kg-hr) or by a peptone meal with acid secretion determined by intragastric titration technique. The methyl PG analogues tested exhibited a profound and prolonged inhibitory action on gastric acid and pepsin secretion induced by pentagastrin. PG analogues caused almost complete inhibition of gastric acid response to a peptone meal with a significant reduction in the serum concentration of immunoassayable gastrin. Except with the highest dose of PG(S)-15-methyl-PGE_2 methyl ester, which caused abdominal discomfort and single episodes of diarrhea in some subjects, no symptoms or untoward biochemical effects were observed. The methylated PG analogues studied are very potent inhibitors of gastric acid and pepsin secretion stimulated by pentagastrin or a meal and may have clinical potential in the treatment of peptic ulcer.

LIBRARY U. OF I. URBANA-CHAMPAIGN

0854 STIMULATION OF GASTRIC ACID SECRETION IN THE DOG BY THE C-TERMINAL PENTA-, TETRA-, AND TRIPEPTIDES OF GASTRIN AND THEIR O-METHYL ESTERS. (Eng.) Lin, T. M.; Southard, G. L.; Spray, G. F. (Lilly Res. Lab., Indianapolis, IN 46206). *Gastroenterology* 70(5):733-736; 1976.

The relative potency of the C-terminal peptides of gastrin, of the *O*-methyl esters of the C-terminal tri- and tetrapeptides, and of the sulfone derivative of the C-terminal tetrapeptide amide on gastric HCl secretion was studied in six dogs. Acid secretion from the vagally innervated gastric fistula of unanesthetized dogs was stimulated in a dose-related manner by the C-terminal penta-, tetra-, and tripeptide amides of gastrin, the *O*-methyl esters of the tetra- and tripeptides, and the sulfone derivative of the tetrapeptide amide. The potency and efficacy of Peptavalon (a substituted pentapeptide) and the C-terminal penta- and tetrapeptide amides were about the same on a weight or molar basis. On a molar basis, the pentapeptide amide was about 4,300 times as potent as the tripeptide amide. The *O*-methyl ester and the sulfone derivative of the tetrapeptide were about equipotent, 1/25 and 1/30, resp., as potent as the tetrapeptide amide. The dipeptides amides did not stimulate acid secretion in a dose range of 50-1,500 μg/kg-hr. The results indicate that (a) the C-terminal tetrapeptide amide cannot be the minimal effective "stump" for biologic activity in the gastrin molecule, (b) the C-terminal amide is important but not essential for gastric stimulating power, and (c) oxidation of the sulfur atom of the methionyl residue in the tetrapeptide does not result in total loss of activity.

0855 INHIBITION OF GASTRIC ACID SECRETION IN MAN BY EXOGENOUS AND ENDOGENOUS PANCREATIC GLUCAGON. (Eng.) Christiansen, J.; Holst, J. J.; Kalaja, E. (Bispebjerg Hosp., Copenhagen, Denmark). *Gastroenterology* 70(5):688-692; 1976.

The interaction of i.v. infused glucagon and pentagastrin on gastric acid secrection was studied in five healthy subjects. In a step dose-response study with pentagastrin (0.01, 0.1, 1.0, and 10.0 μg/kg-hr), the dose required for one-half maximal response (D_{50}) was 130 ng/kg-hr. With this dose of pentagastrin as background stimulation in a step dose-response study with glucagon (0.5, 2.0, 8.0, and 16.0 μg/kg-hr), the dose of glucagon required for one-half maximal inhibition was 1.64 μg/kg-hr. In a third experiment, the dose-response study with pentagastrin was repeated on a background infusion of glucagon in the dose found to be D_{50}. A significant inhibition of acid secretion was found on all dose levels. The inhibition followed noncompetitive kinetics. Plasma concentrations of pancreatic glucagon in four of the five subjects were comparable to concentrations seen after a protein meal. Intravenous infusion of *l*-arginine on a background stimulation of acid secretion with synthetic human gastrin I (250 ng/kg-hr) was performed in seven healthy subjects. Arginine increased serum glucagon concentration to levels seen after a meal, and resulted in a significant inhibition of acid secretion. The results favor the hypothesis that pancreatic glucagon may participate in the physiologic inhibition of gastric acid secretion.

0856 EFFECT OF GROWTH HORMONE RELEASE-INHIBITING HORMONE ON GASTRIC SECRETION, MUCOSAL BLOOD FLOW, AND SERUM GASTRIN. (Eng.) Konturek, S. J.; Tasler, J.; Cieszkowski, M.; Coy, D. H.; Schally, A. V. (Inst. Physiology, 31-531 Krakow, ul. Grzegorzecka 16, Poland). *Gastroenterology* 70(5): 737-741; 1976.

The effect of growth hormone release-inhibiting hormone (GH-RIH) on gastric response to secretory stimulants and on gastric mucosal blood flow and serum gastrin level was studied in four mongrel dogs. GH-RIH, (2.5 μg/kg/hr, i.v.) infusion in the dogs with gastric fistulae and Heidenhain pouches (HP) almost completely inhibited acid and pepsin responses to pentagastrin, urecholine, and a peptone meal. Histamine-induced acid secretion was more resistant to the inhibition by GH-RIH, and only acid secretion evoked by the lower doses of histamine was suppressed by this peptide. The inhibition of pentagastrin-induced gastric secretion was associated with a marked reduction in mucosal blood flow. The ratio of aminopyrine concentration in the gastric juice and blood plasma was not significantly changed by GH-RIH, indicating that the reduction in mucosal blood flow was secondary to an inhibition of gastric secretion. Gastric acid and serum gastrin responses to a peptone meal adjusted to pH 5.0 and kept in the main stomach at this same pH by intragastric titration were significantly decreased by GH-RIH, suggesting that the observed acid inhibition may be attributed in part to suppression of gastrin release. GH-RIH inhibited acid secretion from HP stimulated by liver extract in HP. The finding that GH-RIH inhibits gastric secretion induced by exogenous stimulants as well as by the direct chemical stimulation of the HP mucosa without changing serum gastrin level suggests that the major action of GH-RIH is a direct suppression of the oxyntic glands.

0857 THE GASTRIC RESPONSE TO A TRANSPYLORIC DUODENAL TUBE. (Eng.) Longstreth, G. F.; Malagelada, J. R.; Go, V. L. W. (Mayo Clinic, Rochester, MN 55901). *Gut* 16(10):777-780; 1975.

Five healthy men were studied to determine whether a duodenal tube affects the rate of gastric emptying, acid production, and serum gastrin response following the ingestion of an ordinary solid meal. The duodenal tube and a gastric sump tube were placed after an overnight fast, and the subjects were fed a standardized meal containing about 40% carbohydrate, 40% fat, and 20% protein. Water containing polyethylene glycol (labeled with ^{14}C in two subjects) was also given as a nonabsorbable gastric marker. The total volume of gastric contents and the volume of solid food at the time of complete aspiration were not altered significantly by the presence of a transpyloric tube. The curves for gastric marker concentrations, measured sequentially after the meal, were similar regardless of whether the tube extended into the duodenum or not, but in several subjects, the marker dilution was either consistently greater or consistently less when the tube was in the transpyloric position. Mathematical analysis showed no significant differences in gastric marker concentration, pH, titratable acidity or serum gastrin levels attributable to the transpyloric tube. It is concluded that these tubes do not significantly interfere with gastric responses to an ordinary solid meal.

0858 EFFECT OF CIMETIDINE ON 24-HOUR INTRAGASTRIC ACIDITY IN NORMAL SUBJECTS. (Eng.) Pounder, R. E.; Williams, J. G.; Milton-Thompson, G. J.; Misiewicz, J. J. (Central Middlesex Hosp., London, NW10 7NS, England). *Gut* 17(2): 133-138; 1976.

The effect of p.o. administration of cimetidine, a histamine H_2-receptor antagonist on intragstric acidity was studied in nine normal men. Gastric content pH was measured at hourly daytime and two hourly nighttime intervals for 48 hr. The subjects ate identical meals, drank identical volumes of fluid, and smoked the same number of cigarettes during the two study days. Their physical activity was unrestricted in a ward environment. Blood cimetidine and plasma gastrin were measured in serial blood samples. The subjects were treated in random sequence with cimetidine (0.8-1.0 g) p.o. on one day and placebo capsules on the other. The drug was given in four divided doses: four subjects received it before, and five after, the three main meals. All took the fourth dose at bedtime. Replicate studies in an additional subject given placebo on both study days showed good reproducibility ($r=0.80$, $p<0.01$). Cimetidine therapy decreased intragastric acidity in all subjects. The decrease was similar in the two groups taking the drug before or after meals, mean 24-hr intragastric hydrogen ion activity being lowered by 70 and 72%, resp. Nocturnal anacidity was recorded in only 2 of 45 samples. Administration of cimetidine before meals produced earlier and higher drug blood levels than after meals, but when it was taken after food the blood levels were highest at the time when the buffer capacity of the food was waning. Blood concentrations of cimetidine exceeded the secretory IC_{50} level for most of the time between doses. The results show that cimetidine produces a striking and consistent decrease of intragastric acidity. Although variation in the timing of the dose in relation to meals did not affect the decrease of acidity, the absorption data suggest that patients should take the drug after meals.

0859 INHIBITION OF FOOD-STIMULATED GASTRIC ACID SECRETION BY CIMETIDINE. (Eng.) Pounder, R. E.; Williams, J. G.; Russell, R. C. G.; Milton-Thompson, G. J.; Misiewicz, J. J. (Central Middlesex Hosp., London, NW10 7NS, England). *Gut* 17(3):161-168; 1976.

The effect of 200 mg cimetidine, a new histamine H_2-receptor antagonist, on gastric acid secretion stimulated by a homogenized meal was studied in six normal volunteers using an *in vivo* intragastric titration technique. The subjects were studied twice, no more than 48 hr apart, receiving either cimetidine or placebo in random order. Cimetidine administered either 32 min before (three subjects) or with the meal (three subjects) significantly inhibited gastric acid secretion in all subjects; 96 min after food, total acid secretion decreased by 67 and 57%, resp. When the drug was taken with the meal, absorption was slower (mean peak blood level 2.34 μmol/l, 80-128 min after dosing) than when administered on an empty stomach (mean peak blood level 5.08 μmol/l, 48-64 min after dosing). Blood cimetidine concentration correlated significantly ($p<0.01$) with percentage inhibition of acid output. The calculated concentration resulting in 50% inhibition of gastric acid secretion (IC_{50}) was 1.6 μmol/l. Secretion of gastrin in response to food was unaffected by cimetidine. The results suggest that 200 mg cimetidine effectively inhibits food-stimulated acid secretion and that the bioavailability of the drug may be affected by the timing of dosage in relation to meals.

SECRETION AND METABOLISM

Pancreas

0871 BICARBONATE AND CYCLIC AMP CONTENT OF PURE HUMAN PANCREATIC JUICE IN RESPONSE TO GRADED DOSES OF SYNTHETIC SECRETIN. (Eng.) Domschke, S.; Domschke, W.; Rosch, W.; Konturek, S. J.; Wunsch, E.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nuremberg, Krankenhausstrasse 12, D-852 Erlangen, W. Germany). *Gastroenterology* 70(4):533-536; 1976.

Cyclic AMP and bicarbonate concentrations in pure pancreatic juice were studied to determine their correlation during i.v. infusion of increasing doses of synthetic secretin in seven healthy volunteers (5 men and 2 women, aged 26-44 yr). Pancreatic juice was obtained by endoscopic cannulation of the papilla of Vater. Synthetic secretin was infused i.v. in doses doubled every 20 min. The volume of pancreatic juice was proportional to the log of the secretin dose. A significant rise in pancreatic juice flow was elicited at a dose as low as 8.05 ng/kg/hr. Maximum flow rate approximating 250 µl/5 min/kg was attained during infusion of 129 ng/kg/hr. At the same dose maximal bicarbonate outputs averaging 383 µEq/hr/kg of body weight were obtained, whereas bicarbonate ion concentration approached peak values (135 µEq/ml) at 32.2 ng/kg/hr. Bicarbonate concentrations showed a tendency to fall at supramaximal doses. The effect of increasing secretin doses on bicarbonate and cyclic AMP concentrations was remarkably similar, suggesting the participation of cyclic AMP in human pancreatic bicarbonate secretion.

0872 EFFECTS OF CALCITONIN ON THE SECRETION OF PANCREATIC JUICE INDUCED BY DOPAMINE, SECRETIN AND PANCREOZYMIN. (Eng.) Iwatsuki, K.; Hashimoto, K. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Clin. Exp. Pharmacol. Physiol.* 3(2):159-165; 1976.

The effects of calcitonin on dopamine-, secretin- and pancreozymin-induced pancreatic secretion were investigated in the isolated blood-perfused pancreas of 12 mongrel dogs. The volume of pancreatic secretion induced by pancreozymin given intra-arterially (i.a.) was decreased by an i.a. infusion of 1 U/min of calcitonin, but that induced by dopamine or secretin given i.a. was not affected by calcitonin treatment. Amylase concentration in pancreatic juice either in spontaneous secretion in the resting state or in that of stimulated secretion by pancreozymin was decreased approximately 30% by calcitonin treatment, but amylase concentration in pancreatic juice induced by dopamine or secretin was not affected. Calcitonin had no effect on bicarbonate concentration in pancreatic juice stimulated by these secretagogues. Calcium concentration in pancreatic juice in the resting state was reduced about 36% by calcitonin treatment. Calcitonin caused a decrease in a calcium concentration in the pancreozymin-induced secretion, but did not cause any change in the dopamine- or secretin-induced one. These results suggest that calcitonin may affect the secretory mechanism of the acinar cells but not that of the ductular cells, and that the acinar cells are active even in the resting state.

0873 ROLE OF CHOLINERGIC MECHANISMS IN THE RESPONSE TO SECRETIN OF ISOLATED CANINE PANCREAS. (Eng.) Vaysse, N.; Bastie, M. J.; Pascal, J. P.; Roux, P.; Martinel, Ch.; Lacroix, A.; Ribet, A. (CHU Rangueil Bat L3, 31400 Toulouse Cedex, France). *Gastroenterology* 69(6):1269-1277; 1975.

The effects of carbamylcholine (CCH, 100 μg/hr) and atropine (0.25, 1.0, and 10.0 mg/hr) on the response of the canine exocrine pancreas to secretin (0.1, 0.5, and 5.0 clinic U/hr) were studied using isolated pancreas perfused with whole heparin-treated blood. The pancreas was removed, separated from duodenum, and perfused through the superior mesenteric artery and celiac trunk. Five procedures were followed: 1) a continuous infusion of secretin administered at graded doses (0.2, 1.0, and 10.0 clinic U/hr), 2) a continuous infusion of cholecystokinin (200 μg/hr), 3) a continuous infusion of secretin followed by an infusion of CCH, 4) an infusion of atropine followed by secretin and CCH, and 5) the pancreas was stimulated by CCH or cholecystokin-pancreozymin under a background of secretin. CCH induced a sharper decrease in D_{50} (dose of secretin which elicits half the calculated maximal response) but no increase in maximal response to secretin. This potentiating effect was partially due to vasomotor modifications and chiefly to the action of CCH on the receptor of secretin. Large doses of atropine (10 mg/hr) were necessary to abolish a CCH-induced enzyme response. However, no dose of atropine was able to significantly alter the enzyme response to secretin and/or cholecystokinin-pancreozymin. Although the results indicate that cholinergic tone is not necessay for secretin-induced hydrelatic response to occur, it demonstrates that this cholinergic tone plays a major role in modulating the pancreatic response to a submaximal dose of secretin.

0874 EFFECTS OF SOMATOSTATIN ON PANCREATIC EXOCRINE FUNCTION. INTERACTION WITH SECRETIN. (Eng.) Robberecht, P.; Deschodt-Lanckman, M.; De Neef, P.; Christophe, J. (Brussels Univ. Sch. Medicine, 1000 Brussels, Waterloo Blvd., 115, B-Belgium). *Biochem. Biophys. Res. Commun.* 67(1):315-323; 1975.

The effects of somatostatin on pancreatic hydrolase release, were investigated *in vivo* and *in vitro* in male Wistar rats. α-Amylase was determined in pancreatic fragments by an automated saccharogenic method and lipase by an automated potentiometric single-time-point assay. *In vivo*, a 50 μg/100 g body weight bolus i.v. injection of somatostatin provoked a rapid and significant three- to fourfold increase in amylase and lipase output. The effect remained high for at least 20 min following the injection. *In vitro*, there was a twofold increase 2 min after addition of 10^{-6} M somatostatin; the stimulation persisted for 10 min. The increase was significantly lower than the 3.8- and 5.0-fold increase obtained, resp., with 10^{-6} M secretin and 10^{-6} M pancreozymin. Somatostatin exerted moderate effects on cyclic AMP levels; increases were significant only at 10^{-6} M (+35%). However, somatostatin did inhibit the rise in cyclic AMP induced by secretin. These findings are compatible with the hypothesis that, when utilized alone, somatostatin occupies secretin binding sites and consequently activates adenylate cyclase that may facilitate hydrolase output. When somatostatin and secretin are both present, somatostatin inhibits the effect of secretin on cyclic AMP. The authors conclude that somatostatin is probably an analog of secretin in the exocrine pancreas. It works as an inhibitor or an agonist of secretin depending on peptide concentrations.

Hepatobiliary Tract

0879 CHARACTERIZATION OF RAT LIVER CELL PLASMA MEMBRANES. (Eng.) Fisher, M. M.; Bloxam, D. L.; Oda, M.; Phillips, M. J.; Yousef, I. M. (Dept. Pathology, Univ. Toronto, Toronto, Ontario Canada). *Proc. Soc. Exp. Biol. Med.* 150(1):177-184; 1975.

Preparation of pure fractions of noncanalicular liver cell plasma membranes (PM) and bile canalicular membranes (BCM) of male Wistar rats, based on different behavior in sucrose gradients, is described and some characteristics of the two fractions are reported. Glucose-6-phosphatase activity, normally confined to endoplasmic reticulum, was absent from both BCM and PM, suggesting no microsomal contamination. 5'-Nucleotidase was enriched over 20-fold in the PM and more than 80-fold in the BCM. Leucyl-β-naphthylamidase was located mainly in the BCM fraction. The lower than expected recoveries of 5-nucleotidase activity in the BCM + PM (20% of the total activity in the liver) and leucyl-β-naphthylamidase (5% of total liver activity) was thought to be due to their presence in subcellular elements other than BCM and PM and to losses during preparation. Chemical studies showed BCM to contain more than twice the amount of total lipid on a protein basis than did PM. Total phospholipid and cholesterol were also higher in BCM, but the composition of the phospholipids was similar in both fractions. Polyacrylamide gel electrophoresis of the protein components of the two membranes resulted in more than 20 bands, and differences between the two were apparent. Both fractions contained peptides with apparent molecular weights of 10 x 10^3 to 270 x 10^3. Both membranes contained proteins, mostly less than 160 x 10^3. The differences in lipid and protein composition are thought to be related to the different functions of the two membranes.

0880 CHANGES IN SUBCELLULAR DISTRIBUTION OF *S*-ADENOSYLMETHIONINE DECARBOXYLASE IN REGENERATING AND IN DEVELOPING RAT LIVER. (Eng.) Sturman, J. A.; Gaull, G. E. (Inst. Basic Res. Mental Retardation, Staten Island, NY). *Biochim. Biophys. Acta* 428(1):70-77; 1976.

Distribution of the activity of *S*-adenosylmethionine decarboxylase in homogenates of Nelson-Wistar rat liver regenerating after partial hepatectomy and during development was studied. Total *S*-adenosylmethionine decarboxylase activity was extracted into the supernatant fractions of homogenates in buffer containing Triton X-100. In the stages of rapid growth of liver remaining after partial hepatectomy, an increased activity of *S*-adenosylmethionine decarboxylase in the supernatant fractions was accompanied by a decreased activity in the crude nuclear fractions. In the liver of the developing rat, prior to birth, all activity of *S*-adenosylmethionine decarboxylase was in the supernatant fraction. After birth, activity in the crude nuclear fraction increased rapidly, reaching adult values by the end of weaning. These findings support the hypothesis that *S*-adenosylmethionine decarboxylase in rat liver may have a function other than synthesis of spermidine.

0881 ENERGY WASTAGE IN RATS GIVEN DRUGS THAT INDUCE MICROSOMAL ENZYMES. (Eng.) Pirola, R. C.; Lieber, C. S. (Veterans Admin. Hosp., 130 W. Kingsbridge Rd., Bronx, NY 10468). *J. Nutr.* 105(12):1544-1548; 1975.

Metabolic efficiency was studied in littermate pairs of Sprague-Dawley rats that were given drugs to induce hepatic microsomal enzymes. Rats received a liquid diet containing 36% energy as ethanol, or were injected i.p. with 80 mg/kg/day phenobarbital for 4 days, and/or received 2 i.p. injections 10 hr apart of 100 mg/kg hexobarbital. The presence of an increased metabolic rate was indicated by increases in oxygen consumption and by changes in body weight. In rats fed ethanol, the gain in weight was 26% less than in controls. Treatment with barbiturates increased metabolic rates. In the absence of any drug, induced animals showed a 7.9% greater oxygen consumption than controls. There was a 12.9% increase during hexobarbital anesthesia. Between 8-48 hr after the last injection of phenobarbital, treated rats had a 15% greater weight loss than controls. The results support the hypothesis that hepatic microsomal enzyme induction can significantly alter the body's metabolic efficiency.

0882 COMPUTER SIMULATION OF SULFOBROMOPHTHALEIN KINETICS IN THE RAT USING FLOW-LIMITED MODELS WITH EXTRAPOLATION TO MAN. (Eng.) Montandon, B.; Roberts, R. J.; Fischer, L. F. (Univ. Iowa, Sch. Medicine, Iowa City, IA 52242). *J. Pharmacokinet. Biopharm.* 3(4):277-290; 1975.

A linear, flow limited mathematical model of drug kinetics was used to simulate total BSP kinetics in normal anesthetized male Thorp Sprague-Dawley rats during i.v. infusions (200 nmol/min/kg for 50 min) and following rapid i.v. injections. Four parameters were used to characterize the distribution and biliary and urinary excretion of BSP: liver-to-plasma concentration ratio, extrahepatic tissue-to-plasma concentration ratio, liver clearance rate constant, and renal plasma clearance rate constant. Mean output of BSP in bile was 76%. Only 0.1% of the BSP was found in the urine. Renal plasma clearance was 0.004 ml/min, while hepatic plasma clearance was 3.6 ml/min. The mean concentration of BSP observed in the bile at the end of the infusion was 2600 nmol/ml, while the mean plasma concentration was 9.1 nmol/ml. Results at other infusion rates (50-2400 nmol/min/kg) indicated that there was no apparent saturation of total BSP excretion at these rates. The graphs of the simulated variables fell well within the ranges of observed values. The same model conception and equations that were used for rats were also used to model total BSP kinetics in a 70-kg man. The simulated plasma levels corresponded to the observed plasma levels. The results show that there do not appear to be important differences between the rat and human species in the factors controlling the elimination of BSP from the body.

0883 REGULATION OF PHOSPHOLIPID BIOSYNTHESIS IN ISOLATED RAT HEPATOCYTES. EFFECT OF DIF-
FERENT SUBSTRATES. (Eng.) Sundler, R.; Akesson, B. (Dept. Physiological Chemistry, Univ. Lund, S-220 07 Lund 7, Sweden). *J. Biol. Chem.* 250(9):3359-3367; 1975.

The effects of choline, ethanolamine, and its *N*-methyl analogs, different fatty acids, and L-methionine on phospholipid biosynthesis via the CDP-
ester pathways and the methylation pathway were
studied in rat hepatocytes. Phosphatidylethanol-
amine synthesis was stimulated severalfold by 0.02
to 0.1 mM ethanolamine, especially in the presence
of long chain unsaturated fatty acids. At higher
concentrations of ethanolamine, phosphorylethanol-
amine accumulated, but the level of CDP-ethanolamine
and the rate of phosphatidylethanolamine synthesis
lid not increase further. The rate of phospha-
idylcholine synthesis via the CDP-ester pathway
esponded in a way analogous to that of phosphati-
lylethanolamine synthesis upon the addition of cho-
ine and fatty acid, except that a 10- to 20-fold
igher concentration of choline was required for
aximal stimulation. Phospholipids containing *N*-
onomethyl- or *N*,*N*-dimethylethanolamine were ef-
iciently formed from the corresponding free bases
n the absence of ethanolamine and choline. Eth-
nolamine, but no other bases, completely inhibited
hospholipid formation from *N*-monomethylethanolamine.
he data indicate that the cytidylyltransferase re-
ctions are rate-limiting steps in the synthesis of
hosphatidylethanolamine and probably also phos-
hatidylcholine. The availability of diacylglycerol
nd its fatty acid composition may also significantly
ffect the rate of phospholipid synthesis. The rate
f phosphatidylcholine formation via phospholipid
-methylation approximately doubled when L-methionine
as added at concentrations similar to that in rat
lasma. The rate of phosphatidylcholine synthesis
ia this pathway was 20-40% of that via diacyl-
lycerols and CDP-choline. The methylation of phos-
hatidylethanolamine to phosphatidylcholine remained
ssentially constant when the rate of phosphati-
ylethanolamine synthesis was varied eightfold but
as significantly reduced when the formation of *N*-
onomethyl- or *N*,*N*-dimethylphospholipid was stimulated
addition of the corresponding base. These phospho-
ipids replaced phosphatidylethanolamine as the sub-
rate for methylation and increased the rate of
osphatidylcholine formation via this pathway.

384 THE INFLUENCE OF THE POSITION OF THE OXYGEN DISSOCIATION CURVE ON OXYGEN-DEPENDENT
NCTIONS OF THE ISOLATED PERFUSED RAT LIVER. I.
UDIES AT DIFFERENT LEVELS OF HYPOXIC HYPOXIA.
ng.) Bakker, J. C.; Gortmaker, G. C.; Vrolijk,
C. M.; Offerijns, F. G. J. (Central Lab. Nether-
nds Red Cross Blood Transfusion Service, P.O. Box
90, Amsterdam, The Netherlands). *Pfluegers Arch.*
2(1):21-31; 1976.

The influence of the 2,3-diphosphoglycerate (2,3-DPG) content of RBC on oxygen-sensitive parameters of the liver under conditions of hypoxia was studied. Isolated Wistar rat livers were perfused with fresh and 2,3-DPG-depleted human RBC at different levels of hypoxia. The mean P_{50} values of the measured actual oxygen dissociation curves (ODC) were 24.5 and 18 mm Hg. No changes in flow rate and perfusion pressure occurred under the different experimental conditions. The advantage or disadvantage of a shift of the ODC depended upon the degree of hypoxia, as reflected in the venous pO_2. Perfusions with fresh RBC showed higher venous pO_2 values during normoxia or moderate hypoxia and lower venous pO_2 values at severe hypoxia. A cross-over point was found at a pO_2 of 36 mm Hg in the portal vein. The disadvantage of perfusions with fresh RBC in severe hypoxia was also reflected in higher cytoplasmatic and mitochondrial redox levels. Using bile flow rate as an indirect measure for the rate of hydroxylation-dependent O_2 consumption, a favorable effect of perfusion with fresh RBC was found at a pO_2 of 100 and 40 mm Hg in the portal vein.

0885 SECRETIN-INDUCED BILE SECRETION, BILE ACID OUTPUT AND BLOOD SUPPLY TO THE LIVER IN THE DOG. (Eng.) Brunner, H.; Slat, B.; Kretschmer, G.; Funovics, J.; Grabner, G. (Section of Gastroenterology II, Univ. Vienna, Vienna, Austria). *Eur. Surg. Res.* 7(4/5):205-211; 1975.

Bile secretion and blood flow in the portal vein and the hepatic artery were determined in 16 cholecystectomized anesthetized mongrel dogs before and during continuous infusion of varying doses of secretin. Four groups of four animals were studied, each dog received one dose of secretin: group 1, 0.5 U/kg body weight; group 2, 2 U/kg; group 3, 4 U/kg; or group 4, 8 U/kg. Basal bile flow in the four groups did not differ. Secretin-stimulated flow rose significantly in all cases, but bile acid output was not altered. Basal total liver blood flow of the four groups was equal. Mean hepatic arterial flow was 7.3 ± 1.7 ml/min/kg body weight, while basal portal flow was 32.7 ± 10.4 ml/min/kg. No change in liver blood flow was observed at the lower doses of secretin (0.5 or 2 U/kg). The higher doses, 4 and 8 U/kg, resulted in significant increases of liver blood flow to 46.9 ± 10.4 ml/min/kg and 57.4 ± 25.8 ml/min/kg, resp. Hepatic arterial flow remained unchanged. It is concluded that secretin action on liver blood flow mirrors mainly superior mesenteric arterial vasodilation and seems to be a pharmacologic rather than a physiologic response. Bile secretion is not influenced by changes of hepatic blood flow in the physiologic range.

0886 BILE-SALT METABOLISM IN THE PRIMATE FETUS. (Eng.) Little, J. M.; Smallwood, R. A.; Lester, R.; Piasecki, G. J.; Jackson, B. T. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *Gastroenterology* 69(6):1315-1320; 1975.

Fetal bile salt metabolism was assessed by constant i.v. infusion of trace amounts of $[^{14}C]$cholate

LIBRARY U. OF I. URBANA-CHAMPAIGN

through a fetal jugular vein catheter into six rhesus monkeys over a 6-hr period. The concentration of radiolabel was measured during infusion and for 4 hr after infusion. Radiolabel in bile, plasma, and tissues was assayed by liquid scintillation counting, and individual bile salts in bile, plasma, and tissues were isolated, identified, and quantitated by thin layer and gas liquid chromatography. Placental transfer averaged 30% of the injected dose, while biliary excretion averaged 36%. Of the amount excreted by the fetal liver, 78% was in the form of $[^{14}C]$taurocholate. The findings suggest that bile salt metabolic and excretory mechanism are undergoing developmental maturation at birth.

0887 THE HETEROGENEITY OF DERMATAN SULFATE AND HEPARAN SULFATE IN RAT LIVER AND A SHIFT IN THE GLYCOSAMINOGLYCAN CONTENTS IN CARBON TETRACHLORIDE-DAMAGED LIVER.

(Eng.) Suzuki, S.; Suzuki, S.; Nakamura, N.; Koizumi, T. (Faculty Science, Nagoya Univ., Nagoya 464, Japan). *Biochim. Biophys. Acta* 428(1):166-181; 1976.

Studies were undertaken to demonstrate the occurrence in rat liver of two dermatan sulfate pools, distinguishable by their characteristic composition and their biological properties. The glycosaminoglycan of Sprague-Dawley rat liver can be separated into five distinct fractions; a hyaluronic acid fraction, a heparan sulfate fraction with a molar ratio of sulfate to hexosamine (S/HexN) of approximately 0.7, a heparan sulfate fraction with a S/HexN ratio of about 1.4, a dermatan sulfate fraction with a S/HexN ratio near unity, and a dermatan sulfate fraction with a S/HexN ratio of approximately 1.3. Enzymatic analysis of the two dermatan sulfate fractions indicated that they differ significantly in that the high sulfated fraction contains relatively more *N*-acetylgalactosamine 4,6-bissulfate units (about 26% of the total hexosamine). In experimental injury produced by carbon tetrachloride (rats inhaled CCl_4 for 10 min, twice a week for 8 weeks), the low sulfated fraction increased as much as ninefold on a dry weight basis, bearing no linear relationship to the amount of the high sulfated fraction, which increased only twofold. A significant shift was also observed in the levels of the two heparan sulfate fractions. In this case, however, the high sulfated fraction showed a much more pronounced increase than did the low sulfated fraction. These observations suggest that for each of the dermatan sulfate and heparan sulfate classes, there are at least two pools, distinguished by sulfation degree and perhaps by turnover rate and physiological function.

0888 STUDIES ON THE INHIBITION OF EXPERIMENTAL LIVER FIBROSIS: 2. THE MECHANISM OF THE INHIBITION OF LIVER FIBROSIS OF RATS DUE TO CARBON TETRACHLORIDE BY ELASTASE.

(Eng.) Tsujii, T.; Fukuhara, M.; Fukuda, S.; Matsui, T.; Matsuoka, Y.; Tamura, M.; Morita, T.; Kimura, K.; Moriya, W. (Nara Medical Univ., 840 Shijocho Kashihara Nara, 634 Japan). *Gastroenterol. Jpn.* 10(3):215-224; 1975.

To clarify the mechanism of elastase inhibition of liver fibrosis, the activity of lysosomal enzymes in elastase-treated and untreated male Sprague-Dawley rats was determined during the development of and recovery from liver fibrosis. Chronic liver injury was produced by the s.c. injection of 0.3 ml of olive oil solution of 50% CCl_4/100 g twice weekly. One group of animals was given 0.4 mg/100 g 100% pure elastoproteinase s.c. daily in combination with CCl_4 for 3, 6, 10, 15, and 20 weeks. Another group was given CCl_4 alone until the 10th week, when both substances were administered. A third group was given CCl_4 alone for 20 weeks and then elastase was administered for 4 weeks. Lysosomal enzyme activity was determined by measuring β-glucuronidase, cathepsin, and collagenolytic activity. In addition, elastase was caused to act *in vitro* upon the substrat comprising mixed collagen of acid soluble collagen and neutral soluble collagen extracted from the skin of the guinea pig. No marked differences in lysosomal enzyme activity were noted between any of the elastase-treated groups and those treated with CCl_4 alone. It is concluded that the inhibition of liver fibrosis does not occur through the activation of lysosomal enzyme by elastase. Disc electrophoretic observation of the performance of elastase on the collagen revealed that β-component of collagen disappeared, but that the α-component remained. Thus, inhibition of liver fibrosis by elastase may be due to a direct effect of elastase on the telopeptide portion of collagen.

0889 THE EFFECT OF ETHANOL INGESTION ON THE ALDEHYDE DEHYDROGENASES OF RAT LIVER.

(Eng.) Greenfield, N. J.; Pietruszko, R.; Lin, G.; Lester, D. (Center Alcohol Studies, Rutgers Univ., New Brunswick, NJ 08903). *Biochim. Biophys. Acta* 428(3):627-632; 1976.

The effect of ethanol ingestion on aldehyde dehydrogenase activity in the subcellular fractions of livers from 14 pair-fed male Sprague-Dawley rats was tested. Enzymatic assays were performed at two different concentrations of propionaldehyde (0.068 and 13.6 mM), sufficient to saturate enzymes with high and low affinities for propionaldehyde, resp. The test rats were fed a diet containing ethanol at an average consumption of 12 g/kg/day. During the following day, the control animals received the same diet substituting isocaloric amounts of carbohydrat for the ethanol. These rats were maintained on the diets for about 60 days. The effect of alcohol ingestion varied depending upon the subcellular fraction tested and the concentration of propionaldehyd There was a 60% increase in the activity of aldehyd dehydrogenase with high affinity for propionaldehyd in the mitochondrial membranes. Conversely, there was a 50% decrease in the activity of aldehyde dehydrogenases with high affinity for propionaldehyde in the microsomal fraction. There was also a 58% decrease in the activity of enzymes from the mitochondrial matrix with low affinity for propionaldehyde. The findings suggest that differences in the assay systems employed by previous investigators ma account for the conflicting results on the effect of ethanol feeding.

890 ETHANOL METABOLISM AND LIPID SYNTHESIS BY ISOLATED LIVER CELLS FROM FED RATS. (Eng.)

elmer, J.; Grunnet, N. (Dept. Biochemistry A, Univ.
openhagen, DK-2200 Copenhagen N, Denmark). *Biochim.*
iophys. Acta 428(1):123-137; 1976.

he acute effects of low and high concentrations of
thanol and of fructose, either alone or in combina-
ion with ethanol, on the rate of lipid synthesis
ere studied. The fatty acid synthesis in isolated
iver cells from fed Wistar rats was studied with
ritiated water as the radioactive precursor. The
ells incorporated ^3H_2O at a rate of 1.26 μmol/min/
packed cells. Addition of ethanol caused a 20%
ecrease in the incorporation of tritium into fatty
cids. The decrease was correlated to the increase
the NAD-redox level. The decreased tritium
corporation into fatty acids during ethanol metab-
lism was probably due to a decrease in the specific
tivity of the NADPH used for the synthesis of fatty
ids, rather than to a real inhibition of the fatty
id synthesis. Ethanol oxidation via NADPH-con-
ming pathways and 80 mM ethanol had no effect
on the incorporation of tritium into fatty acids.
uctose (15 mM) inhibited the fatty acid synthesis
75%, and this inhibition was further augmented
ethanol. The isolated rat liver cells oxidized
hanol at a rate of 2.72, 2.93, and 3.48 μmol/min/g
cked cells at 5, 20, and 80 mM ethanol, resp.
uctose had no effect upon ethanol oxidation.
hanol oxidation via the nonalcohol dehydrogenase
thway(s) may involve a transfer of reducing equiv-
ents from mitochondrial NADH to cystolic $NADP^+$,
judged from measurements of metabolite levels.
is is supported by determinations of ^{14}C yield in
ucose from [1-^{14}C]ethanol, and the results are
idence for the presence of hydrogen shuttle activity
ring metabolism of ethanol, catalyzed by the NADH-
pendent alcohol dehydrogenase. A metabolic scheme
proposed to account for the observed changes at
and high concentrations of ethanol.

91 ACUTE EFFECTS OF ORAL AND INTRAVENOUS ETHANOL ON RAT HEPATIC ENZYME ACTIVITIES. (Eng.)

ifel, F. B.; Greene, H. L.; Lufkin, E. G.; Wrensch,
R.; Hagler, L.; Herman, R. H. (Letterman Army
t. Res., Presidio San Francisco, CA 94129). *Bio-*
m. Biophys. Acta 428(3):633-638; 1976.

acute effects of ethanol, alone, and in combina-
n with folic acid, on certain hepatic enzyme ac-
ities and on cyclic AMP concentration were stud-
in male Carworth rats. Administration of 95%
anol (3 ml, 12 ml total volume, p.o.) over a 2-
period significantly decreased plasma glucose
insulin levels and the activities of the gluco-
genic enzymes, pyruvate carboxylase and fructose
hosphatase, and one glycolytic enzyme, fructose-
-P_2 aldolase. In each instance, the p.o. admin-
ration of folate (2,400 μg/day), in conjunction
h the ethanol, prevented these alterations in car-
ydrate metabolism. Intravenous injection of
anol produced a rapid decrease (within 10-15 min)
the activities of hepatic phosphofructokinase,
uvate kinase, fructose diphosphatase, and fruc-
e-1,6-P_2 aldolase. Intravenously administered
anol significantly increased hepatic cyclic AMP
concentration by approximately 60% within 10 min, while p.o. ethanol did not alter hepatic cyclic AMP concentrations. These data confirm the known antagonism between ethanol and folate and suggest that p.o. folate might offer a protective effect against hypoglycemia in rats receiving ethanol.

0892 EFFECTS OF LONG-TERM ETHANOL TREATMENT ON ALDEHYDE AND ALCOHOL DEHYDROGENASE ACTIVITIES IN RAT LIVER. (Eng.)

Koivula, T.; Lindros, K. O. (Dept. Medical Chemistry, Univ. Helsinki, 00170 Helsinki 17, Finland). *Biochem. Pharmacol.* 24(21):1937-1942; 1975.

Effects of long term ethanol administration, either by intubation or as a constituent of the diet, on aldehyde dehydrogenase activity (ADA) in various subcellular fractions of liver were investigated in male Sprague-Dawley rats. The administration by gavage of 5 g ethanol/kg body weight to 11 rats or 6.6 g ethanol/kg to 8 rats for 3 weeks caused weight loss and reduced hepatic ADA in the soluble, mitochondrial, and microsomal fractions. Rats receiving equivalent amounts of ethanol as part of a liquid diet for 5 weeks gained weight and showed no changes in ADA. Alcohol dehydrogenase activity was decreased in the rats treated by gavage and was unchanged in those given ethanol in the diet. However, the rate of ethanol elimination was accelerated in both groups. In the livers of two strains of rats genetically selected for their difference in voluntary alcohol consumption, the mitochondrial and microsomal ADA was shown to be significantly higher in the alcohol-consuming than in the alcohol-avoiding (ANA) rats. Similar differences were found after long term intragastric ethanol administration, although in both strains, the absolute levels of aldehyde dehydrogenase were reduced. Profound reduction of mitochondrial low K_m ADA and high blood acetaldehyde were observed, especially in the ANA rats. This suggests a possible connection between the low activity of this enzyme and the increased acetaldehyde level.

0893 STUDIES ON THE MECHANISM BY WHICH HEPATIC CITRATE SYNTHASE ACTIVITY INCREASES IN VITAMIN B_{12} DEPRIVATION. (Eng.)

Mukherjee, A.; Srere, P. A.; Frenkel, E. P. (Veterans Admin. Hosp., Dallas, TX 75216). *J. Biol. Chem.* 251(7):2155-2160; 1976.

Possible mechanisms that cause increased hepatic citrate synthase activity in vitamin B_{12} deprivation were investigated in Sprague-Dawley rats. Immunochemical titrations of the affinity chromatography-purified enzyme obtained from livers demonstrated that this increased activity was the result of a true increase in enzyme protein content. When fixed ratios of aliquots of normal and B_{12}-deprived rat liver homogenates were mixed, the measured activity showed no change from the expected total citrate synthase activity based on the admixture ratios. Partial purification of the enzyme resulted in the expected recovery of the enzyme at each of the purification steps. Thus, it is unlikely that the change in enzyme activity in B_{12} deprivation was due to the pre-

LIBRARY U. OF I.

sence of a soluble or easily dissociable normally occurring activator or inhibitor. Ouchterlony double diffusion studies, immunochemical titration, and determination of K_m values for oxalacetate and acetyl coenzyme A (substrates for citrate synthase) and K_i values for ATP (inhibitor of citrate synthase) indicated that the enzyme from the B_{12}-deprived livers was structurally the same as that from normal livers. Hepatic citrate synthase degradation rate constants were shown to be essentially unchanged in B_{12} deficiency. The rate of hepatic citrate synthase synthesis, under steady state conditions, was shown to be 2.8-fold greater in the B_{12}-deficient animal than in the normal animal. The increased rate of synthesis appeared to explain the increased enzyme content. Finally, no change in specific activity of the enzyme was seen in brain, heart, or kidney in the B_{12}-deprived animal.

0894 BIOCHEMICAL AND ULTRASTRUCTURAL HEPATIC CHANGES DURING VITAMIN B_{12} DEFICIENCY IN ANIMALS AND MAN. (Eng.) Frenkel, E. P.; Mukherjee, A.; Hackenbrock, C. R.; Srere, P. A. (Southwestern Medical Sch., Dallas, TX 75235). *J. Biol. Chem.* 251 (7):2147-2154; 1976.

Changes in hepatic enzymes of fatty acid synthesis and ultrastructural hepatic changes were studied during vitamin B_{12} deficiency in two patients and in rats. Three groups of rats received a normal diet, a vitamin B_{12}-deficient diet, or a vitamin B_{12}-deficient diet supplemented by i.m. injections of 100 μg of vitamin B_{12} once weekly. Total and specific ATP citrate lyase was nearly threefold greater in the B_{12}-deprived group than in other rats on the normal diet. This increase was also seen in enzymes from hepatic biopsy specimens taken from the two human patients with vitamin B_{12} deficiency. In the rats receiving B_{12} injections, ATP citrate lyase activity was only slightly greater than that seen in the animals on the normal diet. Total and specific activity of hepatic citrate synthase was also found to be increased in B_{12}-deprived animals and man. The activity of hepatic succinate-cytochrome *c* reductase was unchanged in B_{12} deficiency. Vitamin B_{12} deficiency resulted in an increase in hepatic mitochondrial cristae membranes in both rats and man. Histochemical and chemical analysis demonstrated increased glycogen in the liver cells from B_{12}-deficient rats and man. There is thus an increased activity of the otherwise highly constant Krebs cycle enzyme citrate synthase in livers from vitamin B_{12}-deficient animals and humans, and increased mitochondrial cristae membranes.

0895 PROTECTIVE EFFECT OF STEROIDS ON LIVER ISCHEMIA. (Eng.) Delpin, E. A. S.; Figueroa, I.; Lopez, R.; Vazquez, J. (Univ. Puerto Rico Medical Sch., San Juan, Puerto Rico). *Am. Surg.* 41(11):683-695; 1975.

The protective effect of methylprednisone (MP) against ischemia of the liver was studied in 146 rabbits under methohexital anesthesia, and following that, in four human subjects. All animals subjected to occlusion of only the portal vein survived, but when all elements of inflow circulation were occluded for 30 min, the survival was only 10%. However, if MP (30 mg/kg, i.v.) was administered 10-15 min prior to a 30 min occlusion, all animals survived; when drug administration was delayed until after occlusion, only 56% survived. All animals in which occlusion was maintained for 1 hr died, regardless of MP treatment. Eight hr after occlusion, serum levels of alkaline phosphatase, LDH, and SGOT were markedly elevated. LDH and serum bilirubin were more abnormal in the MP-treated animals. At 24 hr after occlusion, all values were approaching normal. Marked histologic changes were observed in the livers of untreated occluded animals by light and electron microscopy, but these changes were minimal in the animals treated with MP. The four human subjects required occlusion of the portal triad for surgical repair. Two were treated with 30 mg/kg MP prior to occlusion and the other two received 1 g each, i.v. It is concluded that MP probably contributed to a smooth and stable early postoperative period.

0896 MODIFICATION OF THE CEREBROVASCULAR RESPONSE TO NORADRENALINE BY BILE DUCT LIGATION. (Eng.) Bloom, D. S.; Eidelman, B. H.; McCalden, T. A. (Univ. Witwatersrand, Hospital St., Johannesburg, South Africa). *Gut* 16(9):732-737; 1975.

The effect of intracarotid infusions of noradrenalin (8-32 μg/min) on the cerebral blood flow was measured by a ^{133}Xe washout technique in 16 adult baboons including 7 who underwent common bile duct ligation 2 weeks before. In normal baboons, 8 and 16 μg/min caused increased grey matter cerebral blood flow, and at 32 μg/min, the rate was slightly below normal. Blood flow was decreased in jaundiced animals with infusion rates of 8 and 16 μg/min, with a return to normal at 32 μg/min. Grey matter cerebrovascular resistance in normal animals was affected only slightly with noradrenalin infusion rates of 8 and 16 μg/min and was increased slightly at 32 μg/min. In jaundiced animals, the grey matter cerebrovascular resistance was increased significantly at 8 and 16 μg/min. Arterial blood pH, pCO_2, and pO_2 did not change significantly during the experiments. In individual animals, there was no good correlation between the size of the cerebrovascular response to noradrenalin and the degree of jaundice or hepatic dysfunction as monitored by usual serum hepatic chemistries. The plasma renin level was not altered significantly in the jaundiced animals. It is suggested that the increased cerebrovascular sensitivity to noradrenalin in obstructive jaundice following bile duct ligation is the result of disturbed smooth muscle uptake mechanisms allowing a greater concentration of the amine at the receptor sites.

0897 THE PROCESS OF CHOLESTEROL CHOLELITHIASIS INDUCED BY DIET IN THE PRAIRIE DOG: A PHYSICOCHEMICAL CHARACTERIZATION. (Eng.) Holzbach, R. T.; Corbusier, C.; March, M.; Naito, H. K. (Gastrointestinal Res. Unit, Cleveland Clinic Foundation, Cleveland, OH). *J. Lab. Clin. Med.* 87(6):987-998; 1976.

olesterol cholelithiasis was induced in 97 prairie gs to observe the physicochemical changes occurring pidly over a short period of time and to correlate ese with degree of biliary cholesterol saturation. addition, the relation between the *in vivo* events duced in prairie dog bile and recently reported obrvations of cholesterol precipitation phenomena in nthetic bile analogs was investigated. Seventy- dogs were fed a 1.2% cholesterol diet and were crificed at intervals over a 14-day period; the maining 25 were used as controls. In previous udies, solutions of physiologically relevant comsition were constructed, which, when plotted cording to convention on a trilinear graph, fell thin the zone of metastable or suspended supersatution. These solutions revealed a consistent and eviously undescribed liquid crystal to solid crys- l phase transition during their approach to equilibum at 37 C; the present *in vivo* studies of prairie g bile, following rapid induction of supersaturaon; revealed identical changes. At first, the sursaturated biles were isotropic followed by a period turbidity and invariable formation of mesophase. ter a few days, the liquid crystals decreased and lid cholesterol crystallites appeared. This *in vitro* rk has predicted not only static, but dynamic prosses as well, with respect to cholesterol precipition, beginning with the metastably supersaturated ate and eventuating in gallstone formation. Ancilry new findings, resulting from the high cholesrol diet, included the induction of human-like hyperlipoproteinemia and rapid hepatocyte degranulation own by electron microscopy.

98 MICROSOMAL DRUG METABOLISM DURING α-NAPHTHYLISOTHIOCYANATE-INDUCED CHOLESTA- S. (Eng.) Drew, R.; Priestly, B. G. (Dept. man Physiology and Pharmacology, Univ. Adelaide, elaide, South Australia 5001). *Toxicol. Appl. armacol.* 35(3):491-499; 1976.

e time course of changes in microsomal metabolism relation to the time course of cholestasis proced by p.o. administration of a single 200-mg/kg se of α-naphthylisothiocyanate (ANIT) was studied male Wistar rats to determine whether a hypotive, hypertrophic smooth endoplasmic reticulum ER) is a causative factor in producing cholestas. The onset and time course of cholestasis as termined by measurement of bile flow did not ange significantly during the first 12 hr after IT. Complete bile stasis was established by 24 and the bile flow returned to the control value ter 7 days. Hexobarbital sleeping time was pronged 1-7 days after ANIT administration, and *in tro* oxidation of aminopyrine and aniline was imired in 10,000 x *g* supernatants of liver homonates from ANIT-treated rats; impaired oxidation s not demonstrated in 105,000 x *g* microsomes om the same animals. Washout of inhibitory conntrations of ANIT or its metabolites during crosome preparation probably accounted for the screpancy between the two *in vitro* preparations ed to assess SER metabolic activity. After olestasis onset, drug oxidation by 105,000 x *g* crosomes was impaired until normal bile flow s re-established. Decreased microsomal cytochrome P-450 paralleled the changes in (105,000 x *g*) microsomal activity, but at no time was microsomal protein yield per gram of liver significantly altered. The data suggest that precholestatic impairment of microsomal drug metabolism was not associated with a hypertrophic, hypoactive SER. Subsequent reversible SER hypoactivity was the result of bile stasis. Elevation of plasma alanine aminotransaminase provided an early index of ANIT hepatotoxicity, while elevation of plasma bilirubin and 5'-nucleotidase was associated with cholestasis and correlated with the diminution and recovery of bile flow.

0899 SUSCEPTIBILITY OF THE LIVER AND BILIARY TRACT TO ANAEROBIC INFECTION IN EXTRAHEPATIC BILIARY TRACT OBSTRUCTION. II. LIVER FUNCTION AND MORPHOLOGY OF THE LIVER AND BILIARY TRACT--AN EXPERIMENTAL STUDY IN RABBITS. (Eng.) Nielsen, M. L.; Asnaes, S.; Stage, J. G. (31 Sofievej, DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 11(1): 73-78; 1976.

The histopathological effects and the effects on liver function of anaerobic biliary tract infection, produced by common duct ligation (cdl) 3 days prior to intravenous bacterial inoculation, were studied in rabbits. Animals were investigated 1, 4, or 7 days after inoculation. Histopathological investigations included the liver, the common duct, and the gallbladder, and liver function was evaluated by bilirubin, alkaline phosphatase (AP), and L-alanine aminotransferase (GPT) in serum. Rabbits with cdl and biliary tract infection were compared to rabbits with cdl in which bacterial inoculation failed to produce infection, to inoculated rabbits without cdl, and to uninoculated rabbits with cdl. Anaerobic biliary tract infection in rabbits with cdl caused a significant increase in liver abscesses, a significantly increased infiltration with granulocytes in the gallbladder, and a significant increase in serum levels of bilirubin, AP, and GPT. However, it failed to produce signs of cholangitis in the liver and intramural abscesses in the gallbladder. It is concluded that in this animal model, biliary tract obstruction produces sufficient anaerobic conditions for obligate anaerobic bacteria to multiply in the bile. In addition, the occurrence and significance of anaerobic bacteria in human biliary tract infections must be re-evaluated.

0935 IMMUNOHISTOCHEMICAL IDENTIFICATION OF THE CHOLECYSTOKININ CELL IN THE INTESTINAL MUCOSA. (Eng.) Buffa, R.; Solcia, E.; Go, V. L. W. (Histopathology, Histochemistry, Ultrastructure Center, Univ. Pavia, Varese, Italy). *Gastroenterology* 70(4):528-532; 1976.

Antibodies against pure porcine cholecystokinin (CCK) obtained from the rabbit were used to selectively stain specific CCK cells in the duodenal and jejunal mucosa of the dog and man. The CCK cells were scattered in the epithelium of the crypts, although some were in the villi. No CCK cells were found in the stomach, pancreas, terminal ileum, or colon. Some pyloric G cells also showed some reactivity with CCK antiserum, but absorption of CCK antiserum with gastrin C terminal pentapeptide prevented the staining of pyloric cells and provided specific staining of intestinal CCK cells. Antihuman gastrin I serum also stained some intestinal cells. Most of these cells did not react when gastrin antiserum was absorbed with pure CCK (a treatment that did not prevent the staining of pyloric gastrin cells). The authors suggest that most gastrin-immunoreactive cells of the intestinal mucosa should be interpreted as cross-reacting CCK cells rather than intestinal gastrin cells.

0936 DIFFERENTIAL REGENERATION OF INTESTINAL PROLIFERATIVE CELLS AND CRYPTOGENIC CELLS AFTER IRRADIATION. (Eng.) Potten, C. S.; Hendry, J. H. (Paterson Lab., Christie Hosp., Manchester M20 9BX, U.K.). *Int. J. Radiat. Biol.* 27(5):413-424; 1975.

The sizes and regeneration kinetics of the total proliferative and cryptogenic populations in mouse jejunum after irradiation are defined. A dose of 900 rad γ-rays to female BD2F$_1$ (Pat) and DBA/2 mice reduced the number of cryptogenic cells (those capable of crypt regeneration) per small intestinal crypt from about 80 to about 2 per surviving crypt. The surviving cells repopulated the crypt, the estimated cell number doubling-time being about 24 hr. On the fourth day after irradiation their numbers were still slightly below normal. The regeneration patterns for cryptogenic and proliferative cells differed significantly over the first 4 days after irradiation. The numbers of proliferative cells fell initially and remained low, while the cryptogenic cells were increasing in number. The low levels persisted for the first 1.5-2 days, after which there was a rapid rise in proliferative cells per crypt with a significant overshoot on the third day and a peak on the fourth day. The number of proliferative cells per crypt in control animals was about twice the number of cryptogenic cells. This ratio was 12 on average after irradiation (days 1-4). These data add support to the hypothesis that the small intestinal crypts contain a subpopulation of stem cells distinct from the proliferative cells.

0937 FATE OF SOLUBLE CARBOHYDRATE IN THE COLON OF RATS AND MAN. (Eng.) Bond, J. H., Jr.; Levitt, M. D. (Veterans Admin. Hosp., Minneapolis, MN 55417). *J. Clin. Invest.* 57(5):1158-1164; 1976.

The fate of glucose in the colon of Sprague-Dawley rats and four healthy men was investigated by measuring breath $^{14}CO_2$ and fecal ^{14}C after direct instillation of ^{14}C-labeled glucose, acetate, and lactate into the cecum. For the 6 hr after administration of up to 400 mg of [U-^{14}C]glucose to the rat and 12.5 g to man, $^{14}CO_2$ excretion was as rapid after intracecal as after intragastric instillation. Less than 20% of ^{14}C, instilled into the cecum as glucose, was recovered in feces, and only about 15% of this fecal ^{14}C was in a dialyzable form. The conversion of intracecally administered glucose to CO_2 was dependent upon the presence of the colonic flora, as evidenced by the minimal excretion of $^{14}CO_2$ after administration of [^{14}C]glucose (200 mg) to germ-free rats. In contrast, acetate and lactate were converted to CO_2 as rapidly in germ-free rats as in their conventional counterparts. Measurement of O_2 availability in the colonic lumen indicated that insufficient O_2 was available for the aerobic metabolism of glucose by the colonic bacteria. These experiments suggest that the colon bacteria anaerobically metabolize most of the glucose to short-chain fatty acids, which are absorbed and oxidized by the host. Most of the remaining fecal glucose is converted to a larger molecular form that has limited osmotic activity. Thus, the colonic flora benefits the host by reducing the osmotic load of nonabsorbed carbohydrate and by making possible the salvage of a large percentage of the calories of carbohydrate, which is not absorbed in the small bowel.

0938 TOPOGRAPHICAL RELATIONSHIP BETWEEN SUCRASE AND LEUCINE β-NAPHTHYLAMIDASE ON THE MICROVILLI MEMBRANE OF RABBIT INTESTINAL MUCOSAL CELLS. (Eng.) Takesue, Y.; Nishi, Y. (Res. Inst. Environmental Medicine, Nagoya Univ., Nagoya, Aichi 464, Japan). *J. Biochem. (Tokyo)* 79(3):479-488; 1976.

The arrangement of the hydrolases on the microvilli membrane of rabbit small intestinal mucosal cells was investigated using antibodies to two hydrolases with different antigenicities, sucrase and β-naphthylaminidase (LNAase). Like anti-sucrase antibody, anti-LNAase antibody quantitatively agglutinated microvilli vesicles. It inhibited the membrane-bound LNAase activity in the same manner as the detergent-solubilized activity. This inhibitory effect of anti-LNAase antibody was not interfered with by monovalent fragments of anti-sucrase antibody. However, the monovalent fragments inhibited vesicle agglutination by anti-LNAase antibody as well as by anti-sucrase antibody. These results indicate that LNAase is located on

he outer surface of microvilli vesicles and suggest
hat LNAase and sucrase are situated in close
roximity on the membrane surface of microvilli
esicles.

939 INTRACOLONIC TENSIONS OF OXYGEN AND CARBON
DIOXIDE IN GERMFREE, CONVENTIONAL, AND
NOTOBIOTIC RATS. (Eng.) Bornside, G. H.; Donovan,
. E.; Myers, M. B. (Louisiana State Univ. Medical
enter, New Orleans, LA 70112). *Proc. Soc. Exp. Biol.*
ed. 151(2):437-441; 1976.

he relation of intracolonic gaseous tension to fecal
icroflora was investigated by mass spectrometric
easurements of intracolonic O_2 and CO_2 in unanes-
hetized germfree, conventional, and gnotobiotic
ischer 344 CDF rats. I.p. measurements were obtained
a rats whose colons became perforated accidentally
12% of the restrained rats) and mean intracolonic
aseous tensions were measured at 5-min intervals.
ecal bacterial flora and cecal size were also deter-
ined. Gnotobiotes were monoassociated with *Escher-*
chia coli, Bacteroides fragilis and *Staphylococcus*
pidermidis, and were diassociated with *E. coli* plus
. fragilis and with *Bacillus macerans* plus an aero-
ic diphtheroid. Mean intracolonic pO_2 in conven-
ional rats (11.1 mm Hg) was significantly lower than
a germfree rats (12.8 mm Hg); mean intracolonic pCO_2
a conventionals (83.4 mm Hg) was greater than in germ-
ree rats (54.6 mm Hg). Differences of pO_2 values
mong all rats were slight. However, intracolonic
CO_2 values were directly related to CO_2 production
 the normal intestinal flora, and were thus sig-
ificantly lower in both germfree and gnotobiotic
ats. I.p. tensions were independent of the status
 rats, and the mean i.p. pO_2 and pCO_2 (38.9 and
.1 mm Hg, resp.) agreed with previously reported
alues. The enlarged cecum, characteristic of germ-
ree rats, was also present in gnotobiotic rats.
ounts of each bacterial species in feces of mono-
ssociated rats were 10^8-10^{10}/g; counts were pro-
ressively smaller in feces of diassociated rats and
onventional rats (10^8-10^9/g and 10^5-10^8/g, resp).
ntracolonic gaseous tensions of CO_2 clearly reflected
e presence of a normal flora in conventional rats
d were inversely proportional to cecal size.

40 PLASMA SECRETIN AND GASTRIN RESPONSES TO
A MEAT MEAL AND DUODENAL ACIDIFICATION
 DOGS. (Eng.) Lee, K. Y.; Tai, H. H.; Chey,
 Y. (Univ. Rochester Sch. Medicine and Dentistry,
chester, NY 14607). *Am. J. Physiol.* 230(3):784-
9; 1976.

 five conscious dogs with gastric fistula and two
odenal cannulas, plasma radioimmunoassay (RIA)
cretin and gastrin levels were determined in
sponse to infusion of 0.1 N HCl in the proximal
odenal cannula, ingestion of a meal, and intra-
odenal infusion of 0.1 N HCl following ingestion
 a meal. Significant increases in plasma RIA
cretin levels occurred during duodenal acidifica-
on. However, no significant change occurred in
e secretin levels after ingestion of a meal,
ereas significant increase in plasma gastrin
vel was observed. Postprandial duodenal pH
remained above 4.5 for 3 hr. In three additional dogs with pancreatic cannula, pancreatic secretion of bicarbonate increased markedly following ingestion of a meal, although the duodenal pH remained above 4.5 and plasma RIA secretin did not change significantly. In the experiments with ingestion of a meal, duodenal infusion of 0.1 N HCl caused significant increases in the secretin levels, but the gastrin levels decreased as the duodenum was acidified. These results indicate that endogenous release of secretin depends on acid pH of the duodenal contents in dogs, but no significant change occurs in the plasma RIA secretin levels after a meal. The increase in the secretin levels and significant decrease in the gastrin levels following duodenal acidification during the postprandial period suggests that increased release of secretin might inhibit endogenous release of gastrin.

0941 STORAGE AND RELEASE OF LABELLED ACETYLCHOLINE IN THE MYENTERIC PLEXUS OF THE GUINEA-PIG ILEUM. (Eng.) Szerb, J. C. (Dept. Physiology and Biophysics, Dalhousie Univ., Halifax, Nova Scotia B3H 4H7, Canada). *Can. J. Physiol. Pharmacol.* 54(1):12-22; 1976.

The existence of the selective activation of two populations of cholinergic neurons in the myenteric plexus of guinea pig ileum was investigated. Guinea-pig ileum myenteric plexus, a longitudinal muscle preparation, was superfused with [^{3}H]choline for 15 min either without being stimulated or during field stimulation at 0.1 or 16 Hz; the preparation was then either removed immediately or after 75- or 135-min superfusion with hemicholinium-3 (HC-3), and the total acetylcholine (ACh) and [^{3}H]ACh contents were determined. The preparation was stimulated for 60 min the second time at 0.1 or 16 Hz in the presence of hemicholinium for the measurement of [^{3}H]ACh release. Exposure to [^{3}H]-choline without stimulation resulted in the formation of [^{3}H]ACh, which decreased without further stimulation in the presence of HC-3 at the same rate as did total ACh. Labeling during 0.1-Hz stimulation resulted in [^{3}H]ACh stores that were maintained in the first 75 min but decreased thereafter. Labeling during stimulation of 16 Hz produced the largest and best maintained [^{3}H]ACh content. Following labeling during 0.1-Hz stimulation, more label could be released than following labeling in the absence of stimulation. Labeling during 16-Hz stimulation did not increase any further the pool of [^{3}H]ACh accessible to release by 0.1-Hz stimulation, but caused a 2.5-times increase in the pool from which 16 Hz stimulation released [^{3}H]ACh. These results suggest that two populations of cholinergic neurons exist in the myenteric plexus, one activated only by high frequency stimulation, the other by both high and low frequency stimulation.

0942 EFFECTS OF CALCIUM ON INTESTINAL MUCIN: IMPLICATIONS FOR CYSTIC FIBROSIS. (Eng.) Forstner, J. F.; Forstner, G. G. (Hosp. Sick Children, Toronto, Ontario, Canada). *Pediatr. Res.* 10(6):609-613; 1976.

LIBRARY U. OF I. URBANA-CHAMPAIGN

Using purified rat intestinal goblet cell mucin as a model mucin, the effect of $CaCl_2$ (1-25 mM) on the physical properties of the mucin were investigated. Isotonicity of incubation media was preserved to mimic *in vivo* conditions. $CaCl_2$ (8-15 mM) caused a 15-33% decrease in viscosity, no change in electrophoretic mobility in acrylamide gels, and a 20-30% decrease in solubility of the mucin. Solubility changes were reversed by the addition of 20 mM EDTA to incubations. Insolubility was also produced in incubations of mucin with a mixture of soluble intestinal contents (NaCl washings). These findings strongly suggest that the mucin became smaller and more dense as calcium was added, a process most probably achieved by loss of intramolecular water.

0943 INTESTINAL LIPOPROTEIN FORMATION: EFFECT OF CHOLCHICINE.

(Eng.) Glickman, R. M.; Perrotto, J. L.; Kirsch, K. (Beth Israel Hosp. and Harvard Medical Sch., Boston, MA 02215). *Gastroenterology* 70(3):347-352; 1976.

Possible microtubule involvement in intestinal lipoprotein formation or secretion was studied by determining the effect of colchicine on intestinal lipid absorption in rats. The effect of colchicine (0.5 mg/100 g) in the lymphatic absorption of $[^{14}C]$-oleic acid was studied in male Holtzman rats with indwelling mesenteric lymph cannulas. Colchicine-treated animals showed a marked delay and a decrease in the lymphatic absorption of $[^{14}C]$oleic acid. Chylomicrons from colchicine-treated animals showed no difference in apoprotein content when examined on sodium dodecyl sulfate polyacrylamide gels. Micellar lipid absorption studied from *in situ* jejunal loops in animals pretreated with colchicine revealed that colchicine administration was associated with a threefold increase in residual mucosal lipid when compared with controls. Thin layer chromatography of residual lipid showed that residual lipid was largely present as triglyceride, suggesting that the impairment in lipid transport induced by colchicine was at a site distal to triglyceride resynthesis. Electron microscopy of intestine from colchicine-treated animals revealed that most residual lipid was present within the endoplasmic reticulum and Golgi in numerous particles the size of chylomicrons (0.2-0.4 μ). These results suggest that the impairment in lipid transport induced by colchicine is distal and, in part, may represent an "exit block." The results also suggest a possible role for microtubules in intestinal lipid transport.

0944 THE INFLUENCE OF HYDROCORTISONE ON THE SYNTHESIS AND TURNOVER OF MICROVILLOUS MEMBRANE GLYCOPROTEINS IN SUCKLING RAT INTESTINE.

(Eng.) Forstner, G.; Galand, G. (Hosp. Sick Children, Toronto, Ontario M5G 1X8, Canada). *Can. J. Biochem.* 54(3):224-232; 1976.

Synthesis and degradation of intestinal mucosal and microvillous membrane glycoproteins were studied in control Wistar suckling rats and suckling rats given cortisol acetate by i.p. injection for 3 days (5.0, 2.5, and 2.5 mg/100 g on postnatal days 10, 11, and 12, resp.). Cortisol acetate had no effect on total uptake of radioactive glucosamine by the protein free compartment of rat intestine. Early incorporation of $[1\text{-}^{14}C]$glucosamine by intestinal glycoproteins was enhanced by cortisol, but stimulation was the same in membrane and homogenate fractions. Polyacrylamide gel electrophoresis of membrane proteins solubilized with 2% sodium dodecyl sulphate demonstrated a cortisol-dependent change, characterized by loss of faster traveling glycoproteins, and a corresponding shift in maximum labeling at 3 hr from these glycoproteins to more slowly migrating glycoproteins. Degradation was studied qualitatively with a double isotope technique. Glycoprotein degradative rates appeared to be stimulated by cortisol, but similarly in membrane and total homogenate fractions. On polyacrylamide gels, the areas occupied by glycoproteins with the highest apparent degradative rates corresponded closely with the areas of most active labeling at 3 hr. The rate of degradation in the most actively labeled zone appeared to be higher after cortisol than in the controls. The results indicate that cortisol does not alter membrane composition by inhibiting degradation of selected glycoproteins, and are consistent with a model in which cortisol stimulates the synthesis of specific membrane glycoproteins in suckling rats, while inhibiting synthesis of other glycoproteins.

0945 EFFECT OF SHIGELLA ENTEROTOXIN ON ELECTROLYTE TRANSPORT IN RABBIT ILEUM.

(Eng.) Donowitz, M.; Keusch, G. T.; Binder, H. J. (Dept. Internal Medicine, Yale Univ., New Haven, CT 06510). *Gastroenterology* 69(6):1230-1237; 1975.

The effect of *Shigella dysenteriae I* enterotoxin on electrolyte transport in rabbit ileal loops was investigated *in vivo* in New Zealand white male rabbits. The findings were compared with those observed in previous studies of ileal mucosa exposed to choleragen. Twenty-eight of 31 loops incubated with shigella enterotoxin in 17 animals were positive, and the mean fluid secreted in the positive loops was 0.65 ± 0.04 ml/cm. The ionic composition was similar to that produced by cholera and *Escherichia coli* enterotoxins. Fluid and electrolyte accumulation occurred *in vivo* and net sodium secretion (-1.0 ± 0.6 $\mu Eq/hr/cm^2$) was present *in vitro* in the enterotoxin exposed tissue in contrast to net sodium absorption in control mucosa. Short circuit current (IsC) was similar in control and toxic tissues. The IsC increased following addition of either 10 mM theophylline, or 0.5 mM dibutyryl cyclic AMP and was similar in enterotoxin exposed and control mucosa. Glucose (10 mM) resulted in a smaller increment of IsC in treated tissue. Mucosal cyclic AMP levels in enterotoxin-exposed mucosa did not differ from those of control. These results demonstrate a difference between the characteristics of rabbit ileal mucosa exposed to shigella or cholera enterotoxin, although both produce electrolyte secretion *in vivo* and *in vitro*. In addition, these studies suggest that cyclic AMP may not mediate the shigella enterotoxin stimulation of intestinal luid and electrolyte secretion as is observed ith cholera enterotoxin-induced intestinal secreion.

946 SHORT CHAIN FATTY ACIDS IN RATS WITH JEJUNAL BLIND LOOPS: I. ANALYSIS OF SCFA N SMALL INTESTINE, CECUM, FECES, AND PLASMA. (Eng.) rizont, R.; Whitehead, J. S.; Kim, Y. S. (Veterans dmin. Hosp., San Francisco, CA 94121). *Gastronterology* 69(6):1254-1264; 1975.

he luminal and plasma levels of short chain fatty cids (SCFA), products of bacterial fermentation, ere measured in male Wistar rats with surgically roduced, self-filling blind loops located in the roximal small intestine. The SCFA content in the mall intestine, plasma, and feces were measured by as chromatography. Acetic, propionic, and butyric cids constituted 95% of SCFA in blind loop segments. or the normal cecum, the isobutyic, isovaleric, and aleric acids constituted 8% of the total fatty cids. Feeding or fasting made little difference. n rats treated with 1 g lincomycin, SCFA were not etected in the blind loop contents, except in one at which had 272 μg of acetic acid. Plasma SCFA onsisted mainly of acetic acid (137 ± 32 μg/ml); he rest were isovaleric (5.2 ± 2.6 μg/ml) and isoutyric (1.4 ± 0.7 μg/ml) acids. Blind loop animals ad nearly twice the concentration of acetic acid in he plasma (240 ± 29 μg/ml) as normal animals. This uggests that endogenous substances may be important ubstrates for the production of SCFA in the inestinal lumen. The high levels of SCFA in the mall intestine and in the feces and the subtantial increase in the concentration of acetic cid in the plasma may aid in the diagnosis of acterial overgrowth syndrome if the same relations re found in man.

GENERAL

53 IS THERE AN ANTRAL-BODY PORTAL SYSTEM IN THE STOMACH? (Eng.) Taylor, T. V.; Torrance, (Manchester Royal Infirmary, Manchester, England). t 16(10):781-784; 1975.

e direction of blood flow from the gastric mucosa s studied in the Wistar rat, with particular atten-on to the relationship between the antrum and the rietal cell mass. A group of rats was given a ngitudinal gastrotomy close to the greater curvature d an intramucosal injection of $Rb^{86}Cl$ was made in e antrum away from the antral-body junction; the ts were killed after 60 sec. In a second group, all ood vessels supplying and draining the stomach were cluded by clamps, but the other procedures remained the same. In a third group, the stomach was divided at the antral-body junction and none of the major feeding vessels along the curvature was interrupted. In a fourth group, the isotope was injected into the mucosa of the stomach body after a longitudinal gastrotomy near the greater curvature. In each case, radioactivity was measured in the liver and in the stomach body. In a fifth group, treated identically to the first group, the duodenum and a strip of terminal ileum were analyzed instead of the liver. In the first group, the radioactivity was transferred from the antrum to the body of the stomach, presumably without passing through the general circulation. Activity in the liver, transmitted by the blood either from the antrum or body of the stomach, was detected.

LIBRARY U. OF I. URBANA-CHAMPAIGN

In the second group, virtually no activity was detected in the body of the stomach, suggesting that the transfer from antrum to body is dependent upon mucosal blood flow. In the third group, after antral exclusion, no activity was transferred to the stomach body, but liver activity was similar to that in the first group. In the fourth group, only a small amount of activity was detected in the antrum. In the fifth group, a small amount of activity occurred in the duodenum, but none occurred in the terminal ileum. The results suggest that a "portal system" exists between the antrum and body of the rat stomach.

0954 FUNCTION OF THE DUCT-LIGATED CANINE PANCREATIC ALLOGRAFT.

(Eng.) Brynger, H.; Bergmark, J.; Claes, G. (Sahlgrenska sjukhuset, Univ. Goteborg, Goteborg, Sweden). *Eur. Surg. Res.* 7(4/5):212-229; 1975.

Heterotropic transplantation of a duct-ligated canine pancreas was performed in 20 previously pancreatectomized, nonrelated recipient mongrel dogs to assess the endocrine function of the gland in the early post-transplantation period. Glucose levels of the 15 dogs surviving after transplantation followed a uniform course. Before pancreatectomy the mean level was 84 mg/100 ml; after transplantation, the blood glucose values normalized within 24 hr. Insulin levels before pancreatectomy were 10 mU/l; after pancreatectomy, the levels decreased significantly to 5 ± 1 mU/l. Initial amylase values showed a mean of 1,520 U/l; after pancreatectomy, the values decreased to 612 U/l. Early endocrine capacity of the transplanted duct-ligated pancreas was satisfactory, restoring the blood glucose in the pancreatectomized recipients to normal levels.

0955 ILEAL CRYPT CELL POPULATION KINETICS AFTER 40% SMALL BOWEL RESECTION: AUTORADIOGRAPHIC STUDIES IN THE RAT.

(Eng.) McDermott, F. T.; Roudnew, B. (Alfred Hosp., Prahran, 3181, Victoria, Australia). *Gastroenterology* 70(5): 707-711; 1976.

Ileal crypt cell population kinetics were investigated by autoradiography with ^{3}H-thymidine in male Sprague-Dawley rats 60 days after resection of a jejunal segment equivalent to 40% of the length of the small bowel. Controls were subjected to transection and anastomosis. The mean total number of cells and the mean number of labeled cells per crypt cell column were estimated. The distribution of proliferating cells was obtained by determining the percentage of labeled cells at each cell position in the crypt cell columns. The cell cycle was analyzed by the method of percentage-labeled metaphases. The mean total number of cells was increased from 30.5 to 36.6 and the mean number of labeled cells per crypt cell column was increased from 10.2 to 12.4. The labeling index was unaltered. The mean sizes of the proliferative and maturation zones were increased. The estimated median duration of the cell cycle was 11.5 hr in the control group and 10.5 hr in the resection group. The duration of DNA synthesis was 6.4 hr in both groups. It is concluded that 40% small bowel resection increases cell renewal by expanding the size of the proliferative zone of the crypt cell population.

0956 INTERSTITIAL FLUID PRESSURE IN CANINE GASTRIC MUCOSA.

(Eng.) Altamirano, M.; Requena, M.; Perez, T. C. (Escuela de Medicina J. M. Vargas, Universidad Central de Venezuela, Caracas, Venezuela). *Am. J. Physiol.* 229(5):1414-1420; 1975.

The interstitial fluid pressure in canine gastric mucosa was measured in mongrel dogs to evaluate the performance of Guyton's small plastic capsules implanted in the submucosa of the gastric corpus. The pressure of the fluid inside the capsule (ICP) was measured between 12-42 days later after mounting the piece of the corpus in a Plexiglas chamber. The capsule was always filled with saline. In two of three experiments, the ICP did not change significantly when the saline was replaced by isotonic glucose or blood plasma. Changes of pressure exerted on the surface of the stomach were accurately monitored by the ICP recordings. Changes of circulation produced by compression of the artery or the vein connected to the piece of mucosa, or by intra-arterial injection of 5 µg epinephrine, 5 µg norepinephrine, 5 µg isoproterenol, or 18% hypertonic mannitol modified the ICP as predicted by Starling's law of capillary filtration. Spontaneous activity of the gastric muscles or the activity, that followed intra-arterial injections of 5-10 µg acetylcholine, 50 µg prostigmine, or large doses of histamine changed the ICP significantly. Intra-arterial atropine usually decreased the ICP by 3-5 mm Hg. The mean value of the ICP in 49 animals was 0.53 ± 0.34 mm Hg; it was negative in 43% of the experiments. It is concluded that the ICP is an accurate estimate of the interstitial fluid pressure of the gastric submucosa.

0957 THE EFFECTS OF CHOLERA ENTEROTOXIN ON INTESTINAL TISSUE WATER AS MEASURED BY NUCLEAR MAGNETIC RESONANCE (NMR) SPECTROSCOPY.

(Eng.) Udall, J. N.; Alvarez, L. A.; Nichols, B. L.; Hazlewood, C. F. (Baylor Coll. Medicine, Houston, TX 77025). *Physiol. Chem. Phys.* 7(6): 533-540; 1975.

The theory that cholera enterotoxin alters the permeability of rat intestinal cells to water was tested by nuclear magnetic resonance (NMR) spectroscopy. Small intestinal loops of male Texas inbred rats were injected with 0.5 ml of either Schwarz/Mann cholera entertoxin (40 µg/cm^3 saline solution) or normal saline. Full thickness segments of intestine from each loop were taken and percentage of water (using a gravimetric procedure that included a correction for fat) and NMR relaxation times were determined. The mean value for tissue water was 79.49% in the controls and 84.52% in the cholera specimens ($p<0.001$). T_1 (spin-lattice) relaxation times were 521.22 ± 69.5 msec in the controls and 667.96 ± 119.25 msec in cholera tissue ($p<0.001$). T_2 (spin-spin) relaxation times were 62.34 ± 9.59 msec in controls and 80.35 ± 21.46 msec in cholera tissue ($p<0.02$). These findings are consistent

h the theory that cholera enterotoxin causes
reased secretion into the lumen of the rat
estine, which is associated with an increase in
sue water.

58 THE EFFECT OF GLUCAGON ON TOTAL LIVER BLOOD
FLOW AFTER OCCLUSION OF THE HEPATIC ARTERY:
TUDY IN ANESTHETIZED, NORMOTENSIVE DOGS. (Eng.)
le, N.; Lim, R. C.; Lindberg, B. (San Francisco
eral Hosp., San Francisco, CA 94110). *Acta Chir.*
nd. 142(1):43-46; 1976.

effect of glucagon in normotensive dogs was
died after occlusion of the hepatic artery. Glu-
on (50 μg/kg, i.v.) significantly increased total
er blood flow 67% in all of six dogs compared to
increase of 3% in four controls. The authors
gest that in man, glucagon treatment may be bene-
ial when occlusion of the hepatic artery becomes
essary during surgery.

9 INCREASED INTESTINAL MUCOSAL TURNOVER AND
RADIOSENSITIVITY TO SUPRALETHAL WHOLE-BODY
ADIATION RESULTING FROM CHOLIC ACID-INDUCED ALTERA-
NS OF THE INTESTINAL MICROECOLOGY OF GERMFREE CFW
E. (Eng.) Mastromarino, A. J.; Wilson, R. (M.D.
erson Hosp., Tumor Inst., 6723 Bertner Ave., Pru-
tial 1801, Houston, TX 77030). *Radiat. Res.* 66
:393-400; 1976.

effect of cholic acid fed to germfree CFW mice on
turnover time of intestinal mucosal cells and on
radiosensitivity to 1,000-10,000 rad whole-body
adiation was investigated. Twenty-eight germfree
25 conventionalized mice received a diet supple-
ted with 0.15% cholic acid for 2 weeks. Six con-
tionalized and eight germfree mice were injected
. with 30 μCi thymidine. In germfree mice on cho-
acid supplementation, the turnover of thymidine-
eled intestinal mucosal cells was significantly
reased and the radiosensitivity to supralethal
le-body irradiation was significantly increased com-
ed to germfree controls. There was a positive cor-
ation between increased survival time after supra-
hal whole-body irradiation and slower intestinal
osal turnover time. Germfree mice supplemented
h cholic acid had intestinal mucosal turnover
es comparable to those of conventionalized controls.
hough cholic acid reduced the mean survival time
germfree mice after supralethal whole-body irradi-
on, the mean survival value was significantly greater than for the conventionalized controls. Supplementing the diet of 26 conventionalized CFW mice with cholic acid did not significantly decrease the intestinal mucosal turnover time nor did it significantly alter their radiosensitivity to supralethal whole-body irradiation. These data suggest that cholic acid is one of the microecological factors responsible for controlling the mucosal renewal rate and the mean survival time after whole-body irradiation.

DIAGNOSTIC PROCEDURES

0965 PRISCOLINE-AUGMENTED HEPATIC ANGIOGRAPHY. (Eng.) Goldstein, H. M.; Thaggard, A.; Wallace, S.; Neiman, H. L. (M.D. Anderson Hosp. Tumor Inst., Houston, TX 77025). *Radiology* 119:275-279; 1976.

Experience with tolazoline hydrochloride (Priscoline) during liver angiography in 26 studies of 25 patients is presented. Two patients were studied for hepatic cysts, and the others had known or suspected metastases from various primary sites. A control angiogram was obtained routinely without a pharmacologic agent. The Priscoline dose was 25-35 mg, injected over a period of 10-15 sec, 30-45 sec prior to the injection of contrast material. Priscoline was of diagnostic value in 8 of the 26 studies. In six cases, the major advantage was increased diagnostic confidence because of significantly improved demonstration of metastases or cyst wall. In several cases, this improvement was manifested as increased hypervascularity and staining of the metastatic nodules, while in several others there was production or accentuation of a hypervascular rim effect about the metastatic lesions. In two cases, Priscoline made the angiographic diagnosis more difficult; a carvernous hemangioma was less opacified, and multiple colonic metastases were less hypervascular. No significant side effects were noted. Priscoline is a useful adjunct to hepatic angiography in the evaluation of space-occupying lesions. Combinations of pharmacoangiography, infusion techniques, and angiotomography may provide the best angiographic accuracy in both the evaluation and staging of hepatic mass lesions.

0966 HEPATIC ANGIOGRAPHY IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Ekelund, L.; Lunderquist, A.; Dencker, H.; Akerman, M. (Dept. Diagnostic Radiology, Univ. Lund, Lund, Sweden). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 126(5):952-956; 1976.

Liver angiography was performed in 13 patients with Crohn's disease and in 3 with ulcerative colitis. Of these patients, 13 underwent liver biopsy (large needle histological biopsy or fine needle aspiration biopsy for cytologic analysis), and the findings were correlated with the results of angiography and biochemical tests. Twelve liver biopsies were abnormal, primarily showing fatty infiltration and reactive hepatitis. Thirteen angiographies were abnormal, with widened and tortuous liver arteries being the most common finding. Liver function tests were within normal limits for all but 3 of the 16 patients, thus correlating poorly with findings of the other tests. Nonhomogeneous hepatograms, observed in seven patients, may indicate a scattered distribution of liver changes and explain why liver biopsy can fail to demonstrate abnormality. These data show that angiography is useful in detecting hepatic abnormality, but evaluation with liver biopsy is necessary to determine the nature of the lesion.

0967 ROUTINE AND BLIND HISTOLOGICAL DIAGNOSES ON COLONOSCOPIC BIOPSIES COMPARED TO CLINICAL-COLONOSCOPIC OBSERVATIONS IN PATIENTS WITHOUT AND WITH COLITIS. (Eng.) Myren, J.; Serck-Hanssen, A.; Solberg, L. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 11(2):135-140; 1976.

To examine the influence of clinical information on the histologic diagnosis, a blind study was made in which colonoscopic biopsies were examined by two pathologists who had no knowledge of the clinical history or findings of patients with and without colitis. The results were then compared to the diagnosis at routine histologic examination and to the clinical-colonoscopic diagnosis. The role of experience in assessing gastrointestinal disease was also examined. Of the 110 patients (64 women and 46 men) examined, complete agreement was found between the blind and routine histologic studies in the sections from 69 patients, between the blind histological study and that of colonoscopy in 66 patients, and between the routine histological diagnoses and those of colonoscopy in 73 patients (66%). The diagnosis of a normal colonic mucosa was made by blind study on colonoscopic biopsies in 32 patients, by the routine study in 36 patients, and by clinical-colonoscopic examination in 40 cases; the percentage of agreement with the colonoscopic diagnosis was 68 and 72, resp. The diagnosis of unspecific nonulcerative colitis was made by the blind histologic study in 43 patients, by the routine histologic examination in 58 cases, and by colonoscopy in 41 patients. The percentage of agreement between the histologic studies and the clinical-colonoscopic diagnoses was 61 and 78, resp. A diagnosis of ulcerative colitis was made by the blind histologic study in 35 patients, by the routine histologic examination in 16, and by colonoscopy in 27 cases. The percentages of agreement between the histologic studies and the diagnoses by clinical-colonoscopic examination were 82 and 59, resp. The differences in symptomatology between groups were small, except for a high occurrence of diarrhea and blood in stool in cases with ulcerative colitis, as evaluated by blind histologic study. These findings stress the importance of following defined criteria for histologic examination.

0968 THE DIAGNOSTIC ACCURACY OF BARIUM STUDIES OF THE STOMACH AND DUODENUM--CORRELATION WITH ENDOSCOPY. (Eng.) Laufer, I.; Mullens, J. E.; Hamilton, J. (McMaster Univ. Medical Centre, Hamilton, Ontario, Canada L8S 4J9). *Radiology* 115:569-573; 1975.

The radiologic and endoscopic findings of 240 patients examined by fiberoptic endoscopy were compared, and the diagnostic accuracy of the standard barium meal was evaluated and compared to the double contrast technique. The patients were divided into two groups according to the type of radiological study performed. In 175 patients examined by a standard barium contrast technique, there were 39 radiological errors (22%). The most common cause of error was failure to detect an abnormality on the radiograph and prominent mucosal folds which could either mask or simulate small lesions. In 65 patients examined by a formal double contrast technique using effervescent pills and a thick barium suspension, there were four radiological errors (6%). In addition, superficial gastric erosions were demonstrated in seven patients. It is concluded that double contrast radiography appears to offer the potential for significant improvements in diagnostic accuracy.

0969 GLUCAGON AND BARIUM ENEMA EXAMINATIONS: A CONTROLLED CLINICAL TRIAL.

(Eng.) Harned, R. K.; Stelling, C. B.; Williams, S.; Wolf, G. L. (Univ. Nebraska Medical Center, Omaha, NB 68105). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 126(5):981-984; 1976.

The effect of glucagon on bowel relaxation and patient discomfort during barium enema examination was assessed in a double-blind crossover clinical trial. Ten healthy volunteers received placebo and 2 mg glucagon i.m. preceding barium enema examination on separate days. In addition, 50 patients were given either placebo or 2 mg glucagon i.m. prior to barium enema examination. The results of 38 variables determined on each study population were similar; when glucagon was given, both the patients and examiners noted significantly less discomfort and more bowel relaxation. There were no significant changes in pulse, blood pressure, or electrocardiogram. Adverse reactions did not occur frequently enough to allow confident comparison of placebo and glucagon. It is concluded that the use of glucagon can provide a more comfortable barium examination with acceptable safety.

0970 FATAL BARIUM INTRAVASATION DURING BARIUM ENEMA.

(Eng.) Cove, J. K. J.; Snyder, R. N. (Kaiser Foundation Hosp., 1510 North Edgemont, Los Angeles, CA 90027). *Radiology* 112(1): 9-10; 1974.

The case of a 64-yr-old woman who died after massive intravasation of barium sulfate suspension during routine barium enema is presented. The patient died almost immediately after a retention catheter had been placed to facilitate barium flow. Autopsy revealed an obstructing inflammatory mass in the sigmoid colon at 15 cm composed of multiple adherent loops of large and small intestine, connective tissue, and fat. Barium sulfate particles were found in many blood vessels throughout the lungs, kidneys, myocardium, duodenum, rectum, myometrium, endocervix, brain, urinary bladder, and perthyroidal fat. A combination of factors may contribute to the occurrence of intravasation of barium sulfate during barium enema, i.e., mucosal inflammation, intestinal obstruction, increased intraluminal pressure, or misplacement of the catheter tip. Symptoms and survival may be related to the amount of barium that enters the systemic circulation, the age and health of the patient, and the timing of the start of resuscitative measures.

0971 INTRAOPERATIVE FINE-NEEDLE BIOPSY AND CYTODIAGNOSIS OF THE TUMORS OF THE PERIAMPULLARY REGION.

(Eng.) Bodner, E.; Lederer, B. (Surgical Clinic, Univ. Innsbruck, Austria). *Chir. Gastroenterol.* 9(3):385-389; 1975.

The value of intraoperative fine-needle aspiration biopsy (with the Franzen-instrumentarium) and cytodiagnosis as a method of improved differentiation of tumorous lesions of the head of the pancreas (carcinoma, chronic pancreatitis) was tested in 71 patients. Out of 52 tumors histologically diagnosed at a later stage (by operation or autopsy), 43 were detected by this method. Two false-negative and no false-positive results were produced. The Franzen puncture caused no complications of any kind. The results indicate that the cytological method affords several advantages (e.g., a higher degree of precision) over the conventional intraoperative frozen section technique, and it fully meets the clinical requirements of rapid diagnosis during operation.

0972 CEA LEVELS IN FLUIDS BATHING GASTROINTESTINAL TUMORS.

(Eng.) Molnar, I. G.; Vandevoorde, J. P.; Gitnick, G. L. (Dept. Medicine, Univ. California, Los Angeles, CA). *Gastroenterology* 70(4):513-515; 1976.

A controlled prospective study was undertaken to compare plasma carcinoembryonic antigen (CEA) levels with CEA levels in fluids that bathe tumors. In addition, the ability of the radioimmunoassay of plasma CEA and CEA in fluids bathing tumors to reveal underlying malignancies of the gastrointestinal tract was assessed. CEA titers were normal (less than 2.5 ng/ml) in the plasma of 42 healthy volunteers. Normal CEA levels were also found in the plasma and in the colonic mucus of 14, the gastric juice of 18, duodenal drainage of 10, and bile of 11 normal control subjects. The colonic mucus of 3 patients with ulcerative colitis, gastric secretions of 5 benign gastric ulcer patients, bile specimens from 11 normal control subjects and from 5 gallstone patients contained CEA at concentrations below 2.5 ng/ml. Positive CEA titers were found in the fluids bathing tumors of all 23 patients with colonic carcinoma, 9/17 patients with gastric carcinoma, and all 6 patients with pancreatic carcinoma. In contrast, positive CEA titers were found in the plasma of only 16 of 23 patients with colon carcinoma, 6 of 17 patients with gastric carcinoma, and 4 of 6 patients with pancreatic carcinoma. Among 46 patients with gastrointestinal malignancies, CEA was detected in significant concentrations in the plasma of 26 patients and in fluids bathing tumors of 38 patients. These results indicate a significant association of adenocarcinoma of the colon with CEA-positive colonic mucus and suggest the usefulness of assaying CEA in fluids bathing tumors for the detection of gastrointestinal malignancies.

0973 PERCUTANEOUS BIOPSY OF CARCINOMA OF THE PANCREAS GUIDED BY ANGIOGRAPHY.

(Eng.) Tylen, U.; Arnesjo, B.; Lindberg, L. G.; Lunderquist, A.; Akerman, M. (Univ. Hosp., Lund, Sweden). *Surg. Gynecol. Obstet.* 142(5):737-739; 1976.

The possibility of obtaining cytologic diagnosis of pancreatic tumors, using selective visceral angiography as a guide for percutaneous, transperitoneal

LIBRARY U. OF I. URBANA-CHAMPAIGN

fine-needle aspiration biopsy, was investigated in 29 patients with pancreatic carcinoma. Positive results of biopsy were obtained in 14 of 18 large tumors (those displaying encasement of extrapancreatic arteries and venous obstruction), in 5 of 7 medium-sized tumors (those causing arterial encasement restricted to pancreatic arteries and venous involvement), and in 3 of 4 small carcinomas (arterial encasement limited to intrapancreatic arteries without venous involvement). The smallest tumor measured 3 cm in diameter. This procedure is recommended whenever histological verification is desired because it is simple and causes no complications.

0974 GASTROESOPHAGEAL (GE) SCINTISCANNING TO DETECT AND QUANTITATE GE REFLUX. (Eng.) Fisher, R. S.; Malmud, L. S.; Roberts, G. S.; Lobis, I. F. (Temple Univ. Health Sciences Center, 3401 N. Broad St., Philadelphia, PA 19140). *Gastroenterology* 70(3):301-308; 1976.

Thirty patients with heartburn and a positive acid-reflux test and 20 normal control subjects were studied to evaluate the use of gastroesophageal (GE) scintiscan in the detection and quantitation of GE reflux. Conventional diagnostic tests including barium esophagography, fluoroscopy, esophagogastroscopy, esophageal biopsy, acid perfusion testing, and esophageal manometry were performed on each patient. None of these techniques was sufficiently sensitive in detecting GE reflux. In contrast, GE reflux was visualized by scintiscanning in 27 of 30 patients. The GE reflux index was significantly greater in reflux patients (11.7), compared to controls (2.7). These studies suggest that GE scintiscanning can quantitate and detect GE reflux accurately, rapidly, noninvasively, and with greater sensitivity than other diagnostic techniques.

0975 ORAL ADMINISTRATION OF A CHYMOTRYPSIN-LABILE PEPTIDE--A NEW TEST OF EXOCRINE PANCREATIC FUNCTION IN MAN (PFT). (Eng.) Gyr, K.; Stalder, G. A.; Schiffmann, I.; Fehr, C.; Vonderschmitt, D.; Fahrlaender, H. (Kantonsspital, CH-4004 Basel, Switzerland). *Gut* 17(1):27-32; 1976.

The usefulness of urinalysis of para-aminobenzoic acid (PABA) following the breakdown of administered N-benzoyl-L-tyrosyl-PABA by chymotrypsin as an index of exocrine pancreatic function was tested in man, and the results were compared with the Lundh test. N-benzoyl-L-tyrosyl-PABA (1 g) was administered p.o. to 24 controls, 15 patients with chronic exocrine pancreatic disease, 13 patients after an attack of acute pancreatitis, 2 patients with gluten-sensitive enteropathy, and 10 patients with biliary tract disease, peptic ulcer, or other disease of the gastrointestinal tract. The Lundh test was also performed in 51 cases. In the normal subjects, a mean of 59.6 ± 12.2% of the peptide-PABA was excreted over a 6-hr period. PABA excretion in the patients with exocrine pancreatic deficiency was significantly less ($p<0.001$) than in controls. With one exception, no overlap of data was noted. In the group with pancreatic deficiency, a significant relation was shown between the new test and the Lundh test. These preliminary data justify further investigation of this procedure as a possible new oral test of exocrine function, especially in chronic pancreatitis.

0976 SOURCES OF THE SERUM ISOAMYLASES AND THEIR NORMAL RANGE OF VARIATION WITH AGE. (Eng.) Skude, G. (Malmo General Hosp., S-214 01 Malmo, Sweden). *Scand. J. Gastroenterol.* 10(6): 577-584; 1975.

The isoamylase patterns of various human tissue homogenates and body fluids were analyzed after electrophoretic separation, and the development of the normal variation of the concentrations of the serum isoamylases during fetal life and childhood were determined. The isoamylase patterns indicated that a significant production of amylase occurred in the salivary glands, the pancreatic gland, and in some organs of the female, but not of the male genital tract. Comparison of the isoamylase pattern of urine with that of serum revealed an increased activity of the main pancreatic isoamylase fraction. The activity of amylase in serum was derived from isoenzymes originating from the salivary glands or the pancreatic gland. A very low activity of the salivary isoamylases was regularly found in serum from 14-week-old fetuses. The activity increased steadily with age and reached the normal adult level, about 80 U/l, at the age of 5 yr. The pancreatic group of isoamylases in serum developed later. There was no demonstrable pancreatic isoamylase activity in the majority of children less than 3 months old. Activity rose slowly to reach adult level at age 10-15 yr. The activity did not vary with sex, and diurnal variation of the isoamylase was negligible. A previous study which found inherited variation of the salivary and pancreatic isoamylase pattern during the first year of life is confirmed by the present investigation.

0977 DIRECT MEASUREMENT OF SERUM NON-CAERULOPLASMIN COPPER IN LIVER DISEASE. (Eng.) Frommer, D. J. (St. Vincent's Hosp., Sydney, N.S.W. 2010, Australia). *Clin. Chim. Acta* 68(3):303-307; 1976.

The serum nonceruloplasmin copper concentrations were measured in 19 normal subjects and in 68 patients with various types of liver disease by a sensitive direct method involving complexing the copper and use of atomic absorption spectrophotometry. In normal subjects the mean concentration (± S.D.) was 10.1 ± 1.6 µg/100 ml, with men having a slightly higher value (10.7 ± 1.3 µg/100 ml) than women (9.2 ± 1.8 µg/100 ml). In five patients with various nonhepatic diseases, concentrations were raised (15.8 ± 8.9 µg/100 ml), as also in 19 patients with hepatitis (14.7 ± 4.3 µg/100 ml), 13 patients with cholestasis (16.1 ± 6.4 µg/100 ml) and 5 patients with cirrhosis (16.3 ± 8.7 µg/100 ml). Thirteen heterozygotes for Wilson's disease and nine patients treated for Wilson's disease had concentrations (12.9 ± 5.9 and 9.8 ± 3.7 µg/100 ml, resp.) that did not differ significantly from normal, whereas four untreated patients had significantly raised concentrations (22.9 ± 4.5 µg/100 ml). The author concludes that direct measurement of serum nonceruloplasmin copper is more accurate than indirect measurement and it may help in assessing the effect of treatment. However, measurement of this fraction of serum copper will not enable Wilson's disease to be differentiated from other forms of liver disease.

0978 GASTRIC PSEUDO-ULCERS: MEMBRANA ANGULARIS AND PYLORIC TORUS DEFECTS. (Eng.) Peavy, P. W.; Clements, J. L., Jr.; Weens, H. S. (Emory Univ. Sch. Medicine, 80 Butler St., S.E., Atlanta, GA 30303). *Radiology* 114(2):591-595; 1975.

Two pseudoniches, pyloric torus and membrana angularis defects, that present as pseudo-ulcerations are described. In the region of the membrana angularis, all three gastric muscle layers (longitudinal, circular, and oblique) are absent or attenuated, creating the bulge seen at fluoroscopy in the prepyloric region. Roentgenographic studies indicate that the bulge appears along the distal lesser curvature even in the normal patient, but changes with peristalsis and usually disappears entirely. Retention of barium during air contrast studies by this niche usually confuses peptic ulcer diagnosis by suggesting a second ulceration or an overestimation of the actual size of the true ulcer. A pyloric torus defect may occur in the midportion of the pyloric canal along the greater or lesser curvature or both. A prolapsed portion, occurring during maximal contraction of the two muscular loops of the pyloric sphincter, creates a transient diamond shaped collection of contrast material during roentgenographic examination in normal patients. A persistent defect may indicate peptic ulcer disease or other conditions causing pylorospasm or hypertrophy. The authors suggest that radiologists can avoid gastric pseudo-ulcers by anticipating the normal variations of the pyloric torus and membrana angularis.

0979 THE CURRENT STATUS OF ANGIOGRAPHY IN GASTROINTESTINAL BLEEDING. (Eng.) Jackson, D. C.; Johnsrude, I. S.; Phillips, J. (Duke Univ. Medical Center, Durham, NC 27710). *J. Can. Assoc. Radiol.* 26(4):266-270; 1975.

ESOPHAGUS

1018 ROENTGEN FINDINGS IN AORTO-ENTERIC FISTULAE.

(Eng.) Wyatt, G. M.; Rauchway, M. I.; Spitz, H. B. (Cincinnati General Hosp., Cincinnati, OH 45267). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 126(4):714-722; 1976.

Roentgenological features are presented from six cases of aorto-enteric fistulas. In three patients (two men and one woman, aged 62-73 yr), the aorta ruptured into the duodenum; in the other three (two women and one man, aged 78-81 yr), it ruptured into the esophagus. The roentgen signs in the three cases with fistulas into the duodenum included primarily extrinsic pressure on the third portion of the duodenum. In one case, the entire duodenum was filled with clot and the tract between the duodenum and the ruptured graft was filled with barium. In other cases, there was effacement of the duodenal folds in the area of extrinsic pressure. This combination of findings in a patient with severe upper gastrointestinal bleeding suggests a fistulous communication. Failure to demonstrate the bleeding point by angiography should not exclude this possibility. Both anteroposterior and lateral aortograms should be obtained if angiography is performed. In two of the cases with aorto-enteric fistulas into the esophagus, there was a mixture of the barium with the laminated clot in the aneurysm. Also, there was loculation of barium outside both the aneurysm and the esophagus in the mediastinum. In one case, the barium flow was obstructed in the esophagus by an apparent intramural defect. In all cases, there was an aneurysm present in the area of the defects with calcification in the wall, making aorto-enteric fistula the most likely diagnosis. Recognition of these signs may permit early diagnosis and subsequent life saving surgical correction.

1019 PEPSIN SECRETION, PEPSINOGEN, AND GASTRIN IN "BARRETT'S ESOPHAGUS." CLINICAL AND MORPHOLOGICAL CHARACTERISTICS.

(Eng.) Mangla, J. C.; Schenk, E. A.; Desbaillets, L.; Guarasci, G. Kubasik, N. P.; Turner, M. D. (Monroe Community Hosp., 435 East Henrietta Road, Rochester, NY 14603). *Gastroenterology* 70(5):669-676; 1976.

The morphological characteristics of Barrett's esophagus in four patients (three men and one woman, aged 51-75 yr) are described. In addition, the notions that this mucosa contains gastrin and that it secretes pepsins under basal conditions are demonstrated for the first time. Three of the patients presented with significant esophageal bleeding and one presented with high esophageal stricture. Baker's tubes with an intragastric balloon were used to prevent reflux; the patients were stimulated with Histalog (β-aminoethyl pyrazole hydrochloride); and esophageal secretions were obtained from three of the four patients. These three did show pepsin in their esophageal secretions. In two cases, the secretions were sufficient to measure pepsin by chemical assay. In one of these, there was an apparent slight increase in acid production after administration of the stimulant, and neither case showed any increase in pepsin output. The esophageal secretion revealed a pattern of proteolytic enzymes on agar gel electrophoresis pH 5.7 different from that of gastric secretion. In one case, the esophageal secretion pattern was very similar to esophageal mucosal patterns. The study also revealed that Barrett's mucosa have even more of the functional characteristics of gastric mucosa. In two cases, esophageal mucosal gastrin was raised 5-10 times above the level in controls with and without hiatus hernia. The mucosa contained either cathepsin or cathepsin and pepsinogens in all cases. The usual clinical treatment of antacids, bedrest, and elevating the head of the bed failed in all of these patients. After Nissen's fundoplication, the bleeding stopped in the two patients who consented to the operation. One patient who repeatedly refused surgery bled for 5 months. Remarkable healing of esophageal mucosa was noted on endoscopy. However, in spite of the dramatic reversion of symptoms, there was no reversion of the mucosa to normal stratified squamous epithelium, and no significant change in esophageal enzyme patterns was seen in a follow-up 9 months and 3 years later. Observations made on multiple biopsies demonstrated that certain types of epithelial cellular elements were constantly present, whereas other cellular elements were variable. The constant elements were the tall columnar epithelial cells and the goblet cells. The inconstant cell types were parietal and chief cells.

1020 PREOPERATIVE ESTIMATION OF ABDOMINAL LYMPH NODE METASTASES OF THE ESOPHAGEAL CARCINOMA.

(Jpn.) Okamoto, Y.; Obitsu, R. (Tokyo Univ. Branch Hosp., Japan). *Gan No Rinsho* 21(2):96-102; 1975.

From examination of 121 surgical cases of esophageal carcinoma, four preoperative x-ray findings were correlated with presence of metastasis to the gastric lymph nodes. The esophagus was divided into upper, middle, and lower sections. Lesions were defined by shape as localized, almost localized, intermediate, and nonlocalized. Sizes of ulcers (over 20 mm deep), intensified shadow in the hilum or paramediastinum, and deformity of the cardia of the stomach were the other three criteria. In the upper esophagus, metastasis was rare when surgical prognosis was good. In the middle esophagus, metastases to the gastric lymph nodes occurred frequently when lesions were intermediate or nonlocalized and at least one of the other three criteria was present. Metastases occurred infrequently in the middle and lower esophagus when lesions were localized or almost-localized and the other three criteria were lacking. In the lower esophagus (not including the cardia), metastases very frequently accompanied x-ray findings of intermediate or nonlocalized lesions. Deformity of the cardia was accompanied by gastric lymph node metastases in 13/15 cases. The authors conclude that these four preoperative x-ray findings

re not sufficiently valid for the definitive estima-
ion of esophageal carcinoma.

021 GASTROESOPHAGEAL INVOLVEMENT IN HERPES SIMPLEX.

(Eng.) Howiler, W.; Goldberg,
. I. (Univ. California Sch. Medicine, San Francisco,
A 94143). *Gastroenterology* 70(5):775-778; 1976.

he case of a 25-yr-old woman with acute myelogenous
eukemia who developed disseminated herpes simplex
nvolving both esophagus and stomach is presented.
ver a 3-yr period, the patient was treated with
ytosine arabinoside, 6-theoguanine, and other immuno-
uppressive drugs. When she received a bone marrow
ransplant, the patient developed an ulcerating labial
esion, diagnosed as herpes type II infection, asso-
iated with tender left inguinal nodes. When epi-
astric discomfort developed, endoscopy disclosed
iscrete vesicles with erythematous bases in the
iddle and distal esophagus and superficial ulcers
n the proximal greater and lesser curvatures of the
omach. Barium-air double contrast radiography re-
ealed multiple, coarse nodules separated by interlac-
g crevices and many shallow ulcers. Biopsy specimens
the gastric and esophageal mucosa, and of the lung,
nowed eosinophilic intranuclear inclusion bodies typi-
l of herpes simplex. The authors conclude that cor-
ct identification of moniliasis or herpes simplex is
portant as each disorder has a specific therapy.

22 ABNORMAL ESOPHAGEAL MOTILITY IN PRIMARY SJOGREN'S SYNDROME.

(Eng.) Ramirez-Mata,
; Pena-Ancira, F. F.; Alarcon-Segovia, D. (Insti-
to Nacional de la Nutricion, San Fernando y Viaducto
alpan, Mexico 22, D. F. Mexico). *J. Rheumatol.*
1):63-69; 1976.

study was conducted to determine whether abnormali-
es of esophageal function occurred in 10 patients
th Sjogren's syndrome, not associated with rheuma-
id arthritis, systemic lupus erythematosus, or pro-
essive systemic sclerosis. Abnormalities were
tected in 9 of the 10 patients. All nine had absent
reduced contractility in the upper third of the
ophagus as compared to normal subjects. Five of
e nine also showed abnormalities in other portions
the esophagus: three had spontaneous biphasic and
iphasic tertiary contractions in the lower two-
irds; in one, the diminished intraluminal pressure
tended down to the middle third; and in one, there
s diminished pressure at the lower esophageal sphinc-
r. All but one of the patients had normal esophageal
entgenographic findings; this patient, with abnormal
traluminal pressure at the lower esophageal sphincter,
s shown to have a diaphragmatic hernia. All of the
ur patients who had Raynaud's phenomena also had eso-
ageal dysfunction. However, there were five patients
th esophageal dysfunction who did not have Raynaud's
enomena. Two of the patients had associated thyroid
sease, probably related to Hashimoto's thyroiditis,
d one had malabsorption syndrome possibly due to
uten enteropathy. The observations indicate that
imary Sjogren's syndrome is associated frequently
th motor dysfunction of the upper third of the
ophagus, which may occasionally extend to lower
gments. This motor dysfunction seems to be a previously unrecognized manifestation of primary Sjogren's syndrome. The high prevalence of lacrimal and salivary gland involvement, as well as of esophageal motor dysfunction, which occurs in the various connective tissue disorders, suggests that these abnormalities may be markers of the immunologic derangement which seems to be their common denominator.

1023 EFFECT OF ORAL METOCLOPRAMIDE ON GASTROESOPHAGEAL REFLUX IN THE POST-CIBAL STATE.

(Eng.) Behar, J.; Biancani, P. (Veterans Admin. Hosp., West Haven, CT 06516). *Gastroenterology* 70(3):331-335; 1976.

The effect of p.o. metoclopramide (15 mg), AlMgOH (30 ml), and placebo on the cumulative duration of gastroesophageal reflux induced by a protein-rich meal was compared in 15 male patients with reflux esophagitis. The metoclopramide was found to be more effective than AlMgOH in reducing the cumulative duration of reflux after placebo over a 3-hr period. The same dose of metoclopramide increased resting lower esophageal sphincter pressures in all 15 patients for at least 1 hr and prevented gastroesophageal reflux after an intragastric acid load (300 ml of 0.1 N HCl) in 8 of 10 patients. However, metoclopramide failed to increase the amplitude of esophageal contractions and acid clearing of the distal esophagus. These findings suggest that p.o. metoclopramide (15 mg) may be valuable in the management of reflux esophagitis.

1024 THE EFFECT OF ORAL AND INTRAVENOUS METOCLOPRAMIDE ON HUMAN LOWER ESOPHAGEAL SPHINCTER PRESSURE.

(Eng.) Cohen, S.; Morris, D. W.; Schoen, H. J.; DiMarino, A. J. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 70(4):484-487; 1976.

Lower esophageal sphincter (LES) pressure was evaluated in response to p.o. or i.v. metoclopramide in eight normal subjects and in eight patients with symptomatic gastroesophageal reflux. Both p.o. and i.v. administration routes of metoclopramide gave a dose-related increase in LES pressure. Complete dose-response curves to the p.o. administered compound showed greater absolute responsiveness in normals as compared to patients with LES incompetence. The generally accepted p.o. dose of 10.0 mg of metoclopramide gave a slight increase in LES pressure that was not consistent in all symptomatic patients. These studies suggest that higher doses of metoclopramide may be required for treating symptomatic gastroesophageal reflux secondary to LES incompetence.

STOMACH

1054 REFLECTION ON OCCULT BLOOD REACTION ON FECES AS THE PRIMARY FILTER IN MASS SURVEY FOR GASTRIC DISEASE. (Jpn.) Umeda, K.; Okamoto, S.; Shintani, Y.; Saitoh, K.; Hara, M.; Kanematsu, H.; Tatara, T.; Iwamiya, K. (Tokyo Medical Coll., Tokyo, Japan). *J. Tokyo Med. Coll.* 32(3):631-636; 1974.

Occult blood reaction in feces was used as the primary filter in a mass survey (5820 men and 296 women) for gastric disease. One-time testing with the benzidine method was conducted, and no diet restrictions were imposed during the test. There were 5195 persons participating in occult blood reaction tests; 852 had positive results (for those 40 yr or older, 523/2015 positive cases). When indirect x-rays were taken on 764 of the positive cases, abnormalities were found in 150 (those 40 yr or older, 102/478 abnormalities). Follow-up examinations on 140 abnormal x-ray cases found 76 trouble-free, 1 gastric sarcoma, 1 gastric carcinoma (stage IIc + III), 12 gastric ulcers, 15 gastric ulcer scars, 4 gastric polyps, 6 duodenal ulcers, 1 polyp in the duodenal region; and 27 other abnormalities. Gastric sarcoma had a low positive occult blood reaction. Gastric ulcer scars, gastric polyps, and the duodenal polyp were discovered incidentally, not as a result of occult blood reactions. Thus, occult blood reaction had very definite limitations as a primary filter. The authors prefer indirect x-rays to identify gastric diseases and recommend mass education about screening examinations.

1055 AN EXPERIMENTAL STUDY ON ATYPICAL EPITHELIAL PROLIFERATIONS ASSOCIATED WITH CHRONIC ULCERATION OF THE STOMACH WITH SPECIAL REFERENCE TO EARLY CARCINOGENESIS. (Eng.) Kanahara, H. (Niigata Univ. Sch. Medicine, Niigata, Japan). *Acta Med. Biol.* 21(3/4):133-168; 1974.

Lantan-gel ulcers and electrocoagulation ulcers were induced in the glandular stomach of 77 Donryu rats and 103 mastomys, and epithelial proliferations associated with the ulceration and chronological changes toward a malignant nature were studied. There were 45 chronic ulcers at the site of treatment with lantan-gel and electrocoagulation and at the site of gastrotomy. In a second experiment, N-methyl-N'-nitro-N-nitrosoguanidine (NG) was used to promote malignant transformation in epithelial proliferations at the margins of chronic ulcers produced in the stomach of Wistar rats and mastomys. Ulcers at the site of the lantan-gel treatment and at the site of gastrotomy showed a higher incidence of chronic lesions than those at the site of electrocoagulation.

LIBRARY U. OF I.

Histologic analysis of chronic ulcerations showed fibroblastic fibrosis associated with particles of lantan-gel and suture material in the ulcer base to be a main cause of interference with ulcer healing. Bethanechol chloride, a parasympathicotonic agent, did not seem to be highly effective for disturbing ulcer healing. A variety of epithelial proliferation associated with chronic ulceration can be histologically divided into regeneration (simple epithelial proliferation), glandular proliferation, adenomatous proliferation, atypical epithelial proliferation, and frankly malignant proliferation in order of chronologic changes. The longer the period of experimental course, the higher the incidence of atypical epithelial proliferation. Lantan-gel ulcers followed by NG administration revealed a considerably high incidence of chronic ulceration. Various grades of atypical epithelial proliferations at the ulcer margin and base were yielded by NG administration to Wistar rats bearing lantan-gel ulcers; four cases of these produced adenocarcinomas. Based on gross appearances, the chronic ulcers were classified into four types: small round ulcer, large round ulcer, large irregular ulcer, and irregularly healing ulcer. In general, small round ulcers were accompanied by regenerative proliferation of the epithelium at the margin, large round ulcers by glandular proliferation or adenomatous proliferation, large irregular ulcers and irregularly healing ulcers by atypical epithelial proliferation. The results suggest that marginal epithelial proliferation of an experimental chronic gastric ulcer possesses the capability of transforming to atypical and, further, to malignant changes.

1056 STUDIES ON INTRA-OPERATIVE RADIOTHERAPY OF GASTRIC CANCER.

(Jpn.) Abe, M.; Yabumoto, E.; Takahashi, M.; Tobe, T. (Kyoto Univ., Kyoto, Japan). *Nippon Acta Radiol.* 34(3):146-154; 1974.

Thirty-eight patients with different stages of gastric carcinoma were treated by intra-operative irradiation on a specially-designed operating table. A pentagonal treatment cone was used that encompassed the lymph node groups along the left gastric, common hepatic arteries and around the celiac axis. Clinical results demonstrated that intra-operative radiotherapy (single dose of 3,500 R with 8 MeV electrons), on localized small lesions that remain after surgery, can lead to cure without damage to normal structures. Minimum irradiation dosage of 3,000 R is necessary; 4,000 R could probably be tolerated when large tumors are involved. When peritoneal metastasis was present, 13/14 patients died within 1 yr and 1/14 within 2 yr. With curative or noncurative surgery, 4/24 (2 cases at stage IV) survived longer than 5 yr. For successful intra-operative radiotherapy, the original cancer site must be removed by gastrectomy. No hepatic or peritoneal metastases must be present. Metastases to the lymph nodes must be limited to the secondary lymph nodes. Radiotherapy is applicable, even when invasion through the serosa to the head of the pancreas is present.

1057 JUVENILE POLYPOSIS AND GASTROINTESTINAL CARCINOMA: A STUDY OF A KINDRED.

(Eng.) Stemper, T. J.; Kent, T. H.; Summers, R. W. (Univ. Iowa Coll. Medicine, Iowa City, IA). *Ann. Intern. Med.* 83(5):639-646; 1975.

Case reports of a kindred having at least 10 members with single or multiple juvenile polyps of the stomach and large intestine, and with 11 members with gastrointestinal carcinoma are presented. The degree of association between juvenile polyps and gastrointestinal carcinoma was investigated. A patient who had had a subtotal colectomy for multiple polyps in 1968 was admitted to the hospital in 1974 for evaluation of abdominal pain. There was considerable evidence of cancer in the immediate family, and a medical history of all relatives was traced through family members, physicians, hospital records, and death certificates. Twenty-three affected members of the family showed a spectrum of involvement by both isolated and multiple juvenile polyps. Two patients had multiple juvenile polyps of the stomach and large intestine, while at least four patients had multiple juvenile polyps of the large intestine. Three patients had only one to four juvenile polyps of the large intestine, and one patient had single polyps of the jejunum and rectum. Another patient had multiple juvenile polyps of the stomach. The earliest age at which symptoms occurred in this kindred was 10 yr. Rectal bleeding and anemia were the most common initial symptoms. The occurrence of both generalized and colonic polyposis in the same kindred suggests that these are different expressions of the same disorder. In this kindred, gastric, duodenal, and cecal carcinomas were relatively common, while there were no cases of primary rectal or sigmoid cancer. The pattern of occurrence of juvenile polyps and carcinoma suggests inheritance by a single autosomal dominant gene with a high degree of penetrance and pleomorphic phenotypes. The disorder is manifested by isolated or multiple polyps in the alimentary tract or carcinoma of various digestive organs, or both, including stomach, duodenum, pancreas, appendix, or colon.

1058 EFFECT OF PROSTAGLANDIN 15(R)15 METHYL-E_2 METHYL ESTER ON ASPIRIN AND TAUROCHOLIC ACID-INDUCED GASTRIC MUCOSAL HAEMORRHAGE IN RATS.

(Eng.) Carmichael, H. A.; Nelson, L.; Russell, R. I.; Chandra, V.; Lyon, A.; Cochran, K. M. (Royal Infirmary, Glasgow, Scotland, G4 OSF). *Gut* 17(1):33-36; 1976.

The effect of p.o. administered prostaglandin 15(R)15 methyl-E_2 methyl ester on aspirin and taurocholic acid-induced gastric mucosal hemorrhage was studied in male Sprague-Dawley rats. The incidence of hemorrhage induced by aspirin (26.7 mM), 64 mg/kg, together with taurocholic acid (2.5 mM), was significantly reduced from 53.6% to 19.5% by the addition of the prostaglandin (9.9 μM). The incidence of hemorrhage induced by aspirin alone (53.3 mM), 128 mg/kg, was significantly reduced from 80% to 20% by the addition of prostaglandin (9.9 μM). These results suggest the possible use of synthetic prostaglandins in the prevention of aspirin-induced gastric pathology.

1059 INVOLVEMENT OF THE GASTRIC ANTRUM IN MENETRIER'S DISEASE.

(Eng.) Olmstead, W. W.; Cooper, P. H.; Madewell, J. E. (Armed Forces Inst. Pathology, Washington, DC 20306). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 126(3):524-529; 1976.

The roentgenologic distribution of enlarged folds in 13 cases of Menetrier's disease are described, and 6 cases of this condition with antral involvement are reported. The corpus, either alone or in combination with another part, was involved more frequently than either the antrum or the fundus. The antrum alone and the fundus alone were affected infrequently, but the antrum in combination with the corpus was involved with moderate frequency (5 of 13 cases). The greater curvature was involved more frequently (85%) than the lesser curvature (54%). Although the already acknowledged higher percentage of greater curvature corpus involvement was again demonstrated (77%), the lesser and greater curvatures of the antrum were affected in almost 50% of the cases. The dominant macroscopic finding was the presence of large, firm folds of gastric mucosa. Gross abnormalities of the submucosa, muscularis propria, and serosa were not found. From the results of this study and earlier studies, the salient histologic feature was thickening of the mucosa from elongation of the tubular gastric glands and deepening of gastric pits; individual cells were not enlarged. This change seems best categorized as hyperplasia and not hypertrophy. In six cases, inflammatory cells were mildly increased in a patchy or diffuse distribution. Results indicate that antral disease should no longer be considered exceptional, especially when other areas of the stomach are involved. Therefore, it is important to include Menetrier's disease in the differential diagnosis of enlarged folds affecting any part of the stomach.

1060 THE INFLUENCE OF BODY TEMPERATURE ON THE PRODUCTION OF ULCERS OF RESTRAINT IN THE RAT.

(Eng.) Antoon, J. W.; Gregg, R. V. (Univ. Louisville Sch. Medicine, Louisville, KY 40201). *Gastroenterology* 70(5):747-750; 1976.

Hypothermia accompanying the production of restraint ulcers in rats was studied to determine if it is causally related to the ulcer. Female Sprague-Dawley rats were restrained for 18 hr while rectal temperatures were monitored with a telethermometer probe. Body temperatures of rats restrained at room temperature fell 5.0 C in the first 5 hr. Gastric ulceration in this group was 100%. When body temperatures were maintained at 38 C, only 26% developed ulcers. The results indicate that depressed body temperature during restraint is causally related to ulceration, and that the degree of hypothermia resulting from restraint correlates well with the severity of ulceration. Prevention of hypothermia reduces the incidence of ulcers.

1061 EFFECT OF FIRST PART OF DUODENUM ON GASTRIC EMPTYING IN DOGS: RESPONSE TO ACID, FAT, GLUCOSE, AND NEURAL BLOCKADE.

(Eng.) Cooke, A. R.; Clark, E. D. (Veterans Hosp., Univ. Iowa, Iowa City, IA 52240). *Gastroenterology* 70(4):550-555; 1976.

The inhibitory role of the first 5 cm of the duodenum on gastric emptying was studied in five dogs given a gastric and a duodenal fistula 5 cm distal to the pylorus. The test meal was instilled (300 ml at 37 C, containing phenol red 40 mg/l) into the stomach and was collected from the duodenal fistula at 1- or 2-min intervals for 10 or 20 min. As the test meal emptied from the stomach, it bathed the first 5 cm of duodenum, stimulating the appropriate receptor. A Foley catheter with an inflated balloon prevented passage into the second part of the duodenum. Test meals of hypertonic glucose (15%, 865 mOsm/kg) or 20 and 80 mM of sodium oleate emptied at the same rate as water when allowed to bathe the first 5 cm of duodenum, whereas test meals of 100 mM of HCl were slowed. Using neural blocking agents, the emptying of water meals was slowed with s.c. atropine sulfate (0.03 and 0.15 mg/kg), i.v. hexamethonium chloride (10 mg/kg), and norepinephrine bitartrate (0.04 mg/kg). The emptying of 100 to 120 mM HCl meals was slowed by s.c. atropine sulfate (0.03 and 0.15 mg/kg), norepinephrine bitartrate (0.04 mg/kg), and the i.v. α-receptor blocking agents phenoxybenzamine HCl (2 mg/kg) and phentolamine (2 mg/kg); was unaffected by i.v. hexamethonium chloride (10 mg/kg); and was unchanged (1.0 mg/kg) or slightly slowed (2.0 mg/kg) by the β-receptor blocker propranolol. In contrast, acid test meals were emptied at the same rate as water when treated with i.v. guanethidine monosulfate (2 mg/kg) or i.m. reserpine (1 mg/kg), indicating that the acid inhibition was mediated by an adrenergic mechanism. The emptying of water meals was unchanged by these two drugs. The authors suggest that the first 5 cm of duodenum contain receptors for inhibiting the emptying of acid but not for fat or hypertonic glucose. The neural blocking studies indicate that the inhibitory effect of acid in the first part of the duodenum is an adrenergic mechanism that appears to be neither α- nor β-receptor-mediated.

1062 DYNAMIC GASTRIC RESPONSE TO EXPANSION BEFORE AND AFTER VAGOTOMY.

(Eng.) Jahnberg, T.; Martinson, J.; Hulten, L.; Fasth, S. (Sahlgren's Hosp., Goteborg, Sweden). *Scand. J. Gastroenterol.* 10(6):593-598; 1975.

The dynamic gastric pressure response to expansion by direct intragastric air insufflation, 30-50 ml/sec, was studied in 12 healthy volunteers, 15 nonoperated ulcer disease patients, and in 20 patients operated upon with antrectomy (5), antrectomy and vagotomy (5), or proximal selective vagotomy (10). A nasogastric tube was inserted with the tip placed in the corpus of the stomach. The tube was connected to the top outlet of a reservoir and then in turn connected to a pressure receptor. Continuous pressure recordings were made during gastric expansion with 500 ml air. Nonoperated individuals accepted gastric expansion without considerable increase of pressure. Antrectomized patients showed a higher basal pressure and a moderate increase of pressure during expansion. Vagotomized patients, including the ones operated upon with proximal selective vagotomy, demonstrated a marked increase of pressure during expansion. The results indicate that vagal dener-

LIBRARY U. OF I. URBANA-CHAMPAIGN

vation of the corpus fundus of the stomach is followed by an impairment of the gastric reservoir function.

1092 ASPECTS OF BASAL GASTRIC SECRETION IN MAN. (Eng.) Saunders, J. H. B.; Thjodleifsson, B.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Dundee, Scotland). *Digestion* 12(3):183-188; 1975.

The effect of experimental manipulation on basal (spontaneous) gastric secretion was studied in 14 patients with duodenal ulcer. The rates of secretion and outputs of acid and pepsin decreased in patients subjected to venesection by 30-50%. In 8 of 11 patients, basal secretion of acid was significantly less ($p<0.05$) after overnight aspiration than when measured immediately after introduction of the aspiration tube in the morning (controls). An overnight indwelling tube, without aspiration, reduced basal secretion of acid in 5/10 subjects compared to controls. Overnight infusion of sodium and potassium chloride raised the output of acid in three subjects to levels greater than those observed in controls. These studies demonstrate that the common technique of detecting abnormal gastric secretory function by measuring basal gastric secretion may be effected by experimental manipulation of the subjects.

1093 DUODENAL ULCERS: EARLY AND LATE ONSET. (Eng.) Lam, S. K.; Ong, G. B. (Queen Mary Hosp., 4 Hong Kong). *Gut* 17(3):169-179; 1976.

A study of 1042 hospitalized duodenal ulcer patients (822 men and 220 women) was undertaken to determine the relation of the age of onset of ulcer dyspepsia with the blood group and with the family history of ulcer dyspepsia. Those patients whose symptoms began in the first two decades of life (early onset patients) contained a significantly larger proportion of blood groups A, B, and AB and a significantly stronger family history of dyspepsia than those whose symptoms began from the fourth decade of life onwards (late onset patients). Blood group O prevailed in the late onset patients, and was associated with a proneness to duodenal ulceration and bleeding, and in the late onset patients, a significant proneness to bleed recurrently and severely. Bleeding was the predominent complication in the early onset patients. There was a significantly increased tendency for the late onset ulcers to perforate, to become stenosed, to cause severe pain, and to be multiple, postbulbar, or giant. While these features did not appear to be related to the effect of aging, the occurrence of associated gastric ulceration and the mortality rate were related. In addition, the results suggest a strong genetic predisposition for early onset ulcers.

1094 CLEARANCE AND ACID-STIMULATING ACTION OF HUMAN BIG AND LITTLE GASTRINS IN DUODENAL ULCER SUBJECTS. (Eng.) Walsh, J. H.; Isenberg, J. I.; Ansfield, J.; Maxwell, V. (UCLA Sch. Medicine, Los Angeles, CA 90024). *J. Clin. Invest.* 57(5):1125-1131; 1976.

Acid-stimulating action and clearance of pure natural human big gastrin (HG-34-I) and little gastrin (HG-17-I) were assessed in four men (mean age 49 yr) with inactive duodenal ulcer (DU) disease. Disappearance half-times for HG-17-I after i.v. infusion (5.2 min) or rapid i.v. injection (6.4 min) were six to eight times shorter than those for HG-34-I (41.5 and 37.8 min, resp.). Studies of clearance of synthetic human little gastrin (HG-17-I) were performed in 3 of these subjects, 8 additional male DU subjects, and 11 normal men. The disappearance half-time of synthetic HG-17-I averaged 6.2 min in both the DU subjects and the normal subjects. This suggests that the clearance of exogenous gastrin is not altered in patients with DU. Acid secretion in response to rapid i.v. injection of HG-34-I reached a higher peak and lasted longer than in response to an equimolar dose of HG-17-I; the total response to HG-34-I was about three times that to HG-17-I. During constant i.v. infusion, acid responses to equimolar exogenous doses of the two peptides were similar but the increment in molar concentration of circulating gastrin was six to eight times greater with HG-34-I than with HG-17-I. Chromatography of serum obtained during infusions of HG-34-I revealed no evidence of conversion to HG-17-I, nor was there any increase in circulating G-34 activity during infusions of HG-17-I. The increment in serum gastrin concentration required to produce half-maximal stimulation of gastric acid secretion (D_{50}) was estimated in each subject for each gastrin from curves relating acid secretion to change in serum gastrin concentration produced by infusion of these peptides. Increases in circulating G-17 and G-34 in response to peptone solution instilled into the stomach, taken together, were equivalent to 1.5 times the D_{50} determined from infusions of G-34 and G-17. Acid secretion during the same time period averaged 55% of maximal rates. Although G-34 comprised approximately 75% of the total molar concentration of circulating gastrin after stimulation, it was estimated to contribute less than half of the acid-stimulating activity.

1095 SERUM GROUP I PEPSINOGEN LEVELS AND THEIR RELATION TO GASTRIC ACID SECRETION IN PATIENTS WITH AND WITHOUT RECURRENT ULCER. (Eng.) Samloff, I. M.; Secrist, D. M.; Passaro, E., Jr. (Harbor General Hosp., Torrance, CA). *Gastroenterology* 70(3):309-313; 1976.

Serum group I pepsinogen (PG I) levels were determined by radioimmunoassay in 15 patients with, and in 27 patients without, recurrent ulcer, after vagotomy and either a gastric resection or a drainage procedure. The mean levels were 151.8 ng/ml in the patients with recurrent ulcer and 79.7 ng/ml in those without recurrence. A recurrent ulcer was present in 6 of 7 patients with an elevated serum PG I (over 175 ng/ml) but not in any of 10 patients with a low serum PG I (under 50 ng/ml). The correlation between serum PG I and peak acid output (PAO) was statistically significant in patients with recurrent ulcer and in those without recurrence. In patients with recurrent ulcer, a serum PG I level within the normal range (50-175 ng/ml) was uniformly associated with a PAO of more than 10 mEq/hr. In contrast, of 10 patients without recurrent ulcer and a normal serum PG I, 8 had a PAO of less than 10 mEq/hr. The results show that the mean level of serum PG I in patients with recurrent ulcer is significantly higher than in symptomatic patients without recurrence, and suggest that a serum PG I level beyond the limits of noraml (50-175 ng/ml) for subjects without operations may have diagnostic significance.

1096 GASTRINS IN TISSUE: CONCENTRATION AND COMPONENT PATTERNS IN GASTRIC, DUODENAL, AND JEJUNAL MUCOSA OF NORMAL HUMAN SUBJECTS AND PATIENTS WITH DUODENAL ULCER. (Eng.) Malmstrom, J.; Stadil, F.; Rehfeld, J. F. (Rigshospitalet, DK-2100 Copenhagen O, Denmark). *Gastroenterology* 70(5):697-703; 1976.

The total concentration of gastrin and distribution of gastrin components were examined in mucosal biopsies from corpus, antrum, duodenum, and jejunum from normal subjects and patients with duodenal ulcer. The concentration was highest in the antrum, 12.1 nmol/g mucosa for normal subjects and 9.0 nmol/g mucosa for duodenal ulcer patients. A steep gradient was found distally: in the proximal duodenum the concentration was 0.1; in the distal duodenum it was 0.02-0.01; and in the proximal jejunum it was less than 0.01 of the antral concentration. In the corpus of the stomach, the concentrations were similar to those found in the jejunum. Gel filtrations showed that most gastrin immunoreactivity was eluted in positions corresponding to serum component II (gastrin-34-like) and III (gastrin-17-like), but immunoreactivity corresponding to all the components present in serum was found. No interference from cholecystokinin was observed in duodenal biopsies. In corpus, antrum, and jejunum, component III was the predominant form, whereas component II made up half of the immunoreactive gastrin in the duodenum. No major differences were observed between normal subjects and duodenal ulcer patients. There was no simple relation between acid secretion and mucosal gastrin concentration, but ulcer patients with the highest acid secretion had the lowest antral content and the highest duodenal content. The relative importance of the various sites of gastrin production remains unknown; however, it is suggested that the duodenum is a less important source than the antrum.

1097 GASTROCOLIC FISTULA COMPLICATING BENIGN UNOPERATED GASTRIC ULCER. REPORT OF FOUR CASES AND REVIEW OF THE LITERATURE. (Eng.) Akwari, O. E.; Edis, A. J.; Wollaeger, E. E. (Mayo Clinic, Rochester, MN). *Mayo Clin. Proc.* 51(4):223-230; 1976.

Four cases of gastrocolic fistula complicating benign unoperated gastric ulcer are reported and the pertinent literature is reviewed. In two of these cases, the symptoms of acute perforation into the colon were the initial presentation of peptic ulcer disease. The other two patients had peptic ulcer symptoms dating back 12 and 68 months, and histories of aspirin ingestion. All 4 patients had watery diarrhea and weight loss. Barium enema examination was diagnostic in each case. The perforating ulcers were all located in the distal stomach on the greater curvature. Although enterostasis was not present, regurgitation of colonic contents probably caused bacterial overgrowth in the small intestine, producing structural and functional damage to the mucosal cells. Gastroscopy of one case revealed frequent fecal eructations at the ulcer site consistent with a gastrocolic fistula. The four patients were in good condition, making the mandatory preoperative preparation relatively easy. It is suggested that the best surgical plan consists of: careful preoperative preparation with blood, albumin, fluids, and electrolytes, when indicated; bowel preparation with cathartics, enemas, and administration of oral antibiotics; and one-stage en bloc hemigastrectomy and resection of the involved segment of colon along with the fistulous tract. The total number of cases of gastrocolic fistulas complicating benign, previously unoperated gastric or duodenal ulcers reported in the English literature is 43. There is an appreciable mortality associated with this condition; seven of the 43 patients (16%) died as a direct consequence of the complication.

1098 THE RELATION BETWEEN FUNCTIONING PARIETAL CELL AND GASTRIN CELL MASSES IN TWO GROUPS OF DUODENAL ULCER PATIENTS. (Eng.) Byrnes, D. J.; Lam, S. K.; Sircus, W. (St. Vincent's Hosp., Darlinghurst, Australia). *Clin. Sci. Mol. Med.* 50(5): 375-383; 1976.

To determine whether the relation between parietal cell mass and gastrin cell mass is a crucial factor in the pathophysiology of duodenal ulceration, serum gastrin concentrations were determined before and after a standardized meal in 28 patients with duodenal ulcer and in 10 normal control subjects. In response to pentagastrin, 13 of the duodenal ulcer subjects secreted acid within the limits of normal, and 15 secreted in excess. The differences in the basal serum gastrin concentrations between normal subjects, acid "normosecretors," and hypersecretors were not statistically significant, but that of the hypersecretors was suggestively low. The integrated gastrin response and peak gastrin responses to meals were higher in duodenal ulcer patients with normal acid secretion than in the hypersecretors, but the values for the latter were not different from normal subjects. Stabilization of intragastric pH by infusion into the antrum of sodium bicarbonate during the test meal response period did not alter the differences between the two ulcer patient groups. A significant inverse correlation existed between the maximal acid output and the integrated gastrin response in both normal subjects and hypersecreting duodenal ulcer patients. The evidence supports the existence of an inverse relation between the functioning parietal cell and gastrin cell masses and shows the gastrin response in normosecreting ulcer subjects to be inappropriately high. It also suggests that excessive vagotonia exerts trophic effects upon both parietal cell mass and gastrin cell mass.

1099 THE EFFECT OF 16,16-DIMETHYL PROSTAGLANDIN E_2 ON MEAL-STIMULATED GASTRIC ACID SECRETION AND SERUM GASTRIN IN DUODENAL ULCER PATIENTS. (Eng.) Ippoliti, A. F.; Isenberg, J. I.; Maxwell, V.; Walsh, J. H. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 70(4):488-491; 1976.

The effect of intragastric and intraduodenal 16,16-dimethyl prostaglandin E_2 (dm PGE_2) on meal-stimulated gastric acid secretion and gastrin release was studied in seven male patients with inactive duodenal ulcer. Compared to placebo, doses of 0.75, 1.00, 1.33, and 1.77 μg/kg of dm PGE_2 instilled into the stomach, inhibited meal-stimulated gastric acid secretion by 61-94%. The 1.00, 1.33, and 1.77 μg/kg doses inhibited acid secretion significantly more than an optimal dose of propantheline bromide. Intragastric dm PGE_2 (1 μg/kg) was significantly more effective than intraduodenal dm PGE_2 (1 μg/kg) in inhibiting both gastric acid secretion and gastrin release. After 1.33 and 1.77 μg/kg, some patients experienced abdominal cramps, or diarrhea, or both, but at doses of 1.00 μg/kg or less, no apparent side effects were observed. It is concluded that 16,16-dm PGE_2 significantly inhibits meal-stimulated gastric acid secretion and gastrin release, and may be of therapeutic value in patients with peptic ulcer disease, provided that it is free of untoward side-effects with chronic administration.

1100 GASTRIC ANTISECRETORY AND ANTIULCER PROPERTIES OF PGE_2, 15-METHYL PGE_2, AND 16,16-DIMETHYL PGE_2: INTRAVENOUS, ORAL AND INTRAJEJUNAL ADMINISTRATION. (Eng.) Robert, A.; Schultz, J. R.; Nezamis, J. E.; Lancaster, C. (The Upjohn

LIBRARY U. OF I. URBANA-CHAMPAIGN

Company, Kalamazoo, MI). *Gastroenterology* 70(3): 359-370; 1976.

The antisecretory property of prostaglandin (PG) E_2 was compared with that of two analogues, 15-methyl PGE_2 and 16,16-dimethyl PGE_2, and the anti-ulcer property of PGE_2 was compared with that of 16,16-dimethyl PGE_2. In dogs prepared with denervated gastric pouches (Heidenhain), 16,16-dimethyl PGE_2 was 100-times and 15-methyl PGE_2 was 40-times more active than PGE_2 in inhibiting gastric secretion stimulated by histamine. The methyl analogues were also more active orally, and their action was of much longer duration than that of PGE_2. Volume, acid concentration and output, and pepsin output were reduced in a dose-dependent manner. None of the PG's appreciably affected pepsin concentration. In female Upjohn rats, depending upon the assay used and the route of administration, 16,16-dimethyl PGE_2 was 2-50 times more potent than PGE_2 and was equal to 15-methyl PGE_2. 16,16-Dimethyl PGE_2 also inhibited gastric secretion and prevented the formation of gastric and duodenal ulcers produced in the rat. When given p.o. in dogs, the PG's often caused vomiting. However, when given intrajejunally or i.v. at antisecretory doses, vomiting seldom occurred. The PG's appear to inhibit gastric acid secretion by acting directly on the parietal cells, making them unresponsive to most stimulants. The results of these studies indicate that 15-methyl PGE_2 and 16,16-dimethyl PGE_2 may be of value in the treatment of peptic ulcer.

1101 STUDIES WITH METIAMIDE IN THE PREVENTION OF DUODENAL ULCERATION IN THE RAT.

(Eng.) Kaplan, E.; Barbezat, G. O.; Millner, G. (Groote Schuur Hosp., Cape Town, South Africa). *Gastroenterology* 70(3):475-476; 1976.

Studies to determine whether metiamide prevents the development of duodenal ulceration induced by s.c. infusion of pentagastrin and bethanechol were conducted in the rat. Ulceration was induced in eight of nine rats given pentagastrin (2.5 µg/kg/min) and bethanechol (12 µg/kg/min) by constant infusion for 48 hr. All showed some histologic abnormality, five of them having panmural duodenal changes. None of the eight rats given these infusions simultaneously with metiamide (156 µg/kg/min) infusion showed macroscopic evidence of duodenal ulceration ($p<0.0005$), and only two showed minimal histological changes (i.e., edema and/or ulceration of tips of only one or two villi). These findings demonstrate that duodenal ulcers induced in rats by s.c. infusions of pentagastrin and bethanechol can be prevented by simultaneous infusion of metiamide.

1102 EFFECTS OF METIAMIDE ON THE HUMAN STOMACH.

(Eng.) Thjodleifsson, B.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Scotland). *Clin. Sci. Mol. Med.* 49(5):445-458; 1975.

The effect of metiamide on gastric acidity was investigated in 17 patients with duodenal ulcer and 4 with esophagitis confirmed endoscopically. Solutions of 200 ml hydrochloric acid or 400 ml glucose were instilled into the stomach and the subsequent rates of gastric secretion and emptying, and the disappearance of acid within the stomach were measured by automatic titration with sodium hydroxide. The Metiamide was given as an i.v. dose of 308 µmol followed by a continuous infusion of 410 µmol/hr. Metiamide inhibited the gastric secretory response to the instilled acid and glucose solutions but did not change the overall pattern of emptying of the instilled solutions. During administration of metiamide, there was a net loss of acid from within the gastric lumen. The rate of disappearance of acid from the instilled acid solution was small and not sufficient to account for the metiamide evoked decrease in the concentration of acid secreted in response to pentagastrin (2.6 nmol for 60 min). It is concluded that metiamide does not inhibit gastric secretion by altering the permeability of the gastric mucosa. The authors propose that the decrease in the acid concentration of gastric juice represents a direct effect of metiamide on the acid-secreting cells of the stomach.

1103 GASTRITIS AND INFLAMMATION OF THE ANASTOMOSIS AFTER GASTRECTOMY FOR ULCERS. RADIOLOGICAL AND ENDOSCOPIC DIAGNOSIS.

(Fre.) Cornet, A.; Barbier, J. Ph.; Henry-Biabaud, E. (Hopital Laennec, 42, rue Sevres, 75340 Paris Cedex 07, France). *Entretiens Bichat Med.* 61-66; 1974.

Ulcer patients (205) who had gastritis and inflammation of the anastomosis after gastrectomy and who underwent endoscopy and gastroduodenal barium transit studies were observed over an 8-yr period. The majority had had a Finster type anastomosis, and the others had been operated upon by the Pean method. No new ulcers or tumors were diagnosed in any of the barium transit studies. In 137 patients, endoscopy revealed many lesions on the gastric stump. The mucous membrane consistently showed two types: the first type was congestive and very inflammed, corresponding to edematous and catarrhal gastritis; in the other type, the membrane was smooth and transparent allowing the vessels of the submucosa to be observed and suggesting typical atrophic gastritis. A total of 115 macroscopic alterations were visible in the 205 endoscopic examinations. Biopsy material obtained from the 205 patients revealed granulomas and 9 cases of carcinoma of the gastric stump. The authors conclude that there was an unusually high incidence (approximately 5%) of gastric carcinoma in ulcer patients who had gastritis and inflammation of the anastomosis after gastrectomy as the incidence of gastric cancer in the general population is only 0.09%.

1104 EFFECT OF VAGOTOMY ON SECRETIN RELEASE IN MAN.

(Eng.) Ward, A. S.; Bloom, S. R. (Sheffield Royal Infirmary, London, England). *Gut* 16(12):951-956; 1975.

The release of secretin by intraduodenal acid was measured by a highly sensitive radioimmunoassay in 12 normal subjects, 23 duodenal ulcer patients, and 14 vagotomized patients (6 after truncal vagotomy and pyloroplasty, 4 after selective vagotomy and pyloroplasty, and 4 after highly selective vagotomy). A highly significant response occurred in all three groups. There was no significant difference between the groups in the magnitude or timing of this response. However, the absolute values for prestimulation and peak secretin were significantly smaller in preoperative duodenal ulcer patients than in either the normal subjects or the vagotomized patients. The secretin response was similar after truncal, selective, and highly selective vagotomy. These results suggest that secretin release is not dependent on intact vagal innervation of the small intestine in man.

1105 VAGOTOMY--A PROSPECTIVE, RANDOMIZED STUDY. (Eng.) Bombeck, C. T.; Condon, R. E.; Nyhus, L. M. (Abraham Lincoln Sch. Medicine, P.O. Box 6998, Chicago, IL 60680). *J. Surg. Oncol.* 7(5):411-414; 1975.

A prospective randomized study of three operations for duodenal ulcer; parietal cell vagotomy alone (without drainage), selective vagotomy with antrectomy, and truncal vagotomy with antrectomy, was conducted. All patients in the study were followed for at least 1 yr and, despite the small number of patients, there was a statistically significant return of gastric secretory activity to preoperative levels in the parietal cell vagotomy group, while both other groups maintained decreased acid secretion at the 1-yr period. There was one recurrent ulcer and one other suspected ulcer in the parietal cell vagotomy group, while both other groups had no ulcer recurrence even though morbidity was higher. This preliminary evaluation suggests strongly that extreme caution be used in applying parietal cell vagotomy alone as a definitive operation for duodenal ulcer.

1106 THE EFFECTS OF HIGHLY SELECTIVE VAGOTOMY ON EXOCRINE PANCREATIC FUNCTION IN MAN. (Eng.) Lindskov, J.; Amtorp, O.; Larsen, H. R. (Bispebjerg Hosp., Bispebjerg Bakke 23, DK 2400 Copenhagen NV, Denmark). *Gastroenterology* 70(4): 545-549; 1976.

Exocrine pancreatic function was studied after meal stimulation and i.v. hormone stimulation with secretin and cholecystokinin in 10 patients with duodenal ulcers before, and 3-4 months after, highly selective vagotomy. Hormone stimulation was also performed in 10 healthy volunteers. Duodenal concentrations of bicarbonate and enzymes after meal stimulation were unaltered postoperatively; e.g., the concentrations of lipase, trypsin, and chymotrypsin were unaltered. The authors conclude that this test is unsuitable for the study of exocrine pancreatic function as no correction of aspirated volumes was possible. However, this correction was possible in the i.v. hormone studies. A gastroduodenal tube with a balloon to occlude the pyloric canal was used, and tracer was infused into the duodenum. Results of this study showed that patients with duodenal ulcer display an increased basal secretion volume and an increased trypsin output during hormone stimulation. After highly selective vagotomy, basal secretion volume fell, tending to normal, while the stimulated secretion volume and bicarbonate and enzyme output were unchanged.

1107 ALCOHOL TOLERANCE AFTER PROXIMAL GASTRIC VAGOTOMY. (Eng.) Moodie, A. F.; Royston, C. M. S.; Spencer, J. (Royal Postgraduate Medical Sch., London, England). *Gut* 16(12):966-967; 1975.

Alcohol tolerance was studied in 10 men after proximal gastric vagotomy (PGV), in 6 men after truncal vagotomy and antrectomy (TV + A), and in 6 normal subjects. An oral alcohol tolerance test, in which the subjects consumed 0.65 g/kg absolute alcohol, was performed before surgery and 4 months after surgery. Alcohol tolerance curves of the control, PGV, and TV + A groups before surgery were similar. The PGV group showed no difference between pre- and postoperative tests. After the TV + A, the peak blood alcohol level achieved was significantly higher than before surgery ($p<0.005$ at 15 min and 20 min) and occurred earlier (at 15 min as compared with 40 min). This early peak fell quickly and returned to the preoperative level within 50 min. The authors suggest that PGV has an advantage over other operations for duodenal ulcer as far as alcohol tolerance is concerned.

1108 POSTPRANDIAL OSMOTIC AND FLUID CHANGES IN THE UPPER JEJUNUM AFTER TRUNCAL VAGOTOMY AND DRAINAGE IN MAN. (Eng.) Temple, J. G.; Birch, A.; Shields, R. (Hope Hosp., Salford, England). *Gut* 16(12):957-960; 1975.

Studies were undertaken to determine whether the upper jejunum receives osmotically irritating fluid after truncal vagotomy and drainage, and the relation of this phenomenon to post vagotomy diarrhea. The osmotic pressure and nonabsorbable marker dilution occurring in the upper jejunal lumen after ingestion of a hyperosmotic, EDTA-containing meal were measured in 30 patients after vagotomy and in 13 subjects with no previous gastric operation. Thirteen of the former group had diarrhea at least 3 months after operation. There were no significant differences between the osmolalities measured in any of the patients with or without diarrhea after vagotomy, and concentrations of ^{51}Cr-EDTA were similar to the group without surgery. It is concluded that when diarrhea is encountered after truncal vagotomy and drainage, it is not due to a vast outpouring of fluid into the jejunal lumen in response to the emptying of osmotically irritating fluid into the upper small bowel.

SMALL INTESTINE

1144 ANGIOGRAPHIC EVALUATION OF CARCINOID TUMORS OF THE SMALL INTESTINE: THE VALUE OF EPINEPHRINE. (Eng.) Goldstein, H. M.; Miller, M. (M.D. Anderson Hosp., Univ. Texas System Cancer Center, Houston, TX 77025). *Radiology* 114(1):23-28; 1975.

Angiographic findings in five cases (three women and two men) of histologically proven carcinoid tumors of the ileum are discussed. In the two cases in which epinephrine (12-16 µg) was injected, tumor staining of the primary lesions and their hepatic metastases was markedly enhanced. The findings

LIBRARY U. OF I.

included irregularity and narrowing of the distal mesenteric and intestinal arcade arterial branches, minimal parenchymal stain, and obstructed venous return. A stellate arterial configuration was not seen. Small i.v. doses of epinephrine or other pressor amines accentuate or produce flushing in patients suspected of having small intestinal carcinoid tumors. This effect may be a result of the injected epinephrine circulating to the tumor and stimulating the formation of a flush-provoking humoral substance (i.e., kallikrein or bradykinin). The authors suggest that the possible pharmacoangiographic mechanism of epinephrine may be analogous to the use of secretin and other hormonal pancreatic stimulants to augment pancreatic angiography.

1145 ENTEROKINASE AND TRYPSIN ACTIVITIES IN PANCREATIC INSUFFICIENCY AND DISEASES OF THE SMALL INTESTINE.

(Eng.) Lebenthal, E.; Antonowicz, I.; Schwachman, H. (Harvard Medical Sch., Boston, MA). *Gastroenterology* 70(4):508-512; 1976.

The activities of mucosal and intraluminal enterokinase, trypsin activity, and disaccharidase activities were compared in 133 infants with a variety of gastrointestinal and pancreatic disorders, and the results were correlated with the morphological appearance of the intestinal mucosa. In addition, two patients with congenital enterokinase deficiency are described. Fourteen patients with diarrhea and grade II mucosal injury revealed a significant reduction of enterokinase, trypsin, and disaccharidase activities as compared to 59 children with normal mucosa. Nine patients with cystic fibrosis and pancreatic insufficiency had normal mucosal enterokinase activity and elevated intraluminal enterokinase activity with very low or no trypsin activity. Patients with hypoproteinemia and gastrointestinal protein loss, associated with intestinal lymphangiectasia (four patients) and intestinal lymphoid nodular hyperplasia (three patients), had normal or insignificant decrease of enterokinase and trypsin activities. In patients with steatorrhea, a normal sweat test, normal intestinal mucosa, and absent trypsin activity, two entities were defined. One group (three patients) was diagnosed as Shwachman-Diamond syndrome with pancreatic insufficiency and normal mucosal and intraluminal enterokinase activity. The second group (two patients) with absent mucosal and intraluminal enterokinase activity and normal lipase and amylase activities was diagnosed as congenital enterokinase deficiency. The results indicate a reduction in enterokinase activity that parallels the degree of intestinal mucosal injury and the decrease in disaccharidase activities.

1146 PROXIMAL JEJUNAL REVERSAL PROCEDURE WITHOUT INTERPOSITION FOR MANAGEMENT OF DUMPING SYNDROME.

(Eng.) Chang, T. H.; Myers, H. C. (Broaddus Hosp., Philippi, WV). *Am. Surg.* 41(10):632-639; 1975.

A new surgical procedure, proximal jejunal reversal based on a modified Roux-en-Y without interposition of the jejunal loop, for control of disabling dumping syndrome is described, and its application in three cases is reported. A 72-yr-old woman underwent a 75% gastrectomy for a large gastric ulcer. After gastrojejunostomy, a side-to-side anastomosis was made between the afferent and efferent jejunal loops 10 cm from the gastrojejunal junction, and the efferent loop was then obliterated by suture. Postoperatively, there were no dumping symptoms and a gastrointestinal series revealed slow emptying of the gastric pouch and slow intestinal transit. A bilateral truncal vagotomy and hemigastrectomy with the proximal jejunal reversal procedure were carried out in a 46-yr-old woman for duodenal and pyloric ulcer. The reversed segment measured 10 cm. Four weeks postoperatively, barium studies revealed slow evacuation of the gastric pouch and slow transit of the media. Two yr after a pyloroplasty and bilateral truncal vagotomy for a long-standing duodenal ulcer, a hemigastrectomy with gastrojejunostomy and proximal jejunal reversal were performed for recurrent duodenal ulcer in a 41-yr-old woman. Postoperatively, a gastrointestinal series revealed slow evacuation of the gastric pouch and delayed transit of barium throughout the small intestine. The advantages of this new procedure appear to reside in its simplicity and broad applicability

1147 RECURRENT PNEUMOPERITONEUM DUE TO JEJUNAL DIVERTICULOSIS: WITH A REVIEW OF THE CAUSES OF SPONTANEOUS PNEUMOPERITONEUM.

(Eng.) Wright, F. W.; Lumsden, K. (Churchill Hosp., Oxford OX3 7LJ, England). *Clin. Radiol.* 26(3):327-331; 1975.

A case of recurrent spontaneous pneumoperitoneum due to jejunal diverticulosis in a 72-yr-old man is presented. Symptomless spontaneous pneumoperitoneum is uncommon in the absence of abdominal operative procedures. He presented with a 4-week history of acute pain in the right upper abdomen, associated with abdominal distension. Plain abdominal and chest films showed free gas in the peritoneal cavity and distension of the small bowel. Barium studies revealed multiple large diverticula in the jejunum, and sigmoidoscopy was negative. Serum folic acid was 2.7 x 10^{-9} g/ml, B_{12} was 130 x 10^{-12} g/ml, and fecal fat was elevated. Chemical findings suggested bacterial colonization of the diverticula. Treatment with tetracycline resulted in subjective improvement, and following monthly vitamin B_{12} injections, his stools became firmer and fecal fat decreased. Two further episodes of abdominal pain and radiographic evidence of air in the peritoneal cavity occurred 7 and 17 months after the initial episode, but when seen after 20 months he was feeling well, had a good appetite, had 1-2 stools per day, and had normal chemistries. Six other cases of jejunal diverticulosis with pneumoperitoneum are briefly summarized. Other causes of symptomless pneumoperitoneum include pneumatosis intestinalis, perforation in tabes dorsalis or coma, stercoral ulceration, physiological pneumoperitoneum in women due to exercise in the knee-elbow position, and vaginal douches with a bulb syringe or effervescent fluid.

148 JEJUNAL MORPHOLOGY AND MUCOSAL ENZYME ACTIVITY FOLLOWING INTESTINAL SHUNT OPERATION OR OBESITY. (Eng.) Dano, P.; Nielsen, O.; Petri, .; Jorgensen, B. (Rigshospitalet, Copenhagen, Denark). *Scand. J. Gastroenterol.* 11(2):129-134; 1976.

illous morphology and enzyme activity in the jejunal ucosa were investigated in 33 patients following inestinal shunt operation for obesity. Jejunal biopies were obtained p.o. with a Rubin capsule before nd on an average of 17 months after operation. he shunt left 48 cm of functioning intestine with arious jejunum/ileum ratios. Biopsies revealed a ignificant decrease in protein content from 10.3% efore operation to 5.9% after operation. There was statistically significant increase in alkaline hosphatase, and there was no change in surface area r volume of the villi. It is concluded that weight tabilization observed after this operation is due o adaptive compensation in the ileal remnant.

149 CERTAIN METABOLIC CONSEQUENCES OF JEJUNOILEAL BYPASS. (Eng.) Bendezu, R.; Wieand, R. G.; Green, S. G.; Hallberg, M. C.; Marsters, . W. (St. Luke's Hosp., Cleveland, OH 44104). *Am. . Clin. Nutr.* 29(4):366-370; 1976.

wenty-nine patients were evaluated for possible etabolic alterations after jejunoileal bypass. here was a rapid weight loss during the immediate ostoperative period, associated with a hypercataolic state. Afterward, a more gradual and sustained oss occurred, with a tendency to plateau. Twelve onths after the operation, the average weight loss as 32.2%. Significant decreases in serum cholesterol, serum triglycerides, blood sugar after a gluose load, and fasting plasma insulin levels were oted. Increased oxalate excretion and occasional pisodes of hypomagnesemia also occurred. It is ecommended that this surgical procedure be regarded s palliative, individual, and experimental.

150 EARLY CHANGES IN THE SERUM ACTIVITY OF ORNITHINE CARBAMOYL TRANSFERASE IN PAIENTS OPERATED ON WITH A JEJUNO-ILEAL BY-PASS FOR XTREME OBESITY. (Eng.) Lundstrom, B.; Gillquist, . (Univ. Hosp., Linkoping, Sweden). *Acta Chir. cand.* 141(8):786-789; 1975.

erum activity of ornithine-carbamoyl-transferase S-OCT) was monitored in 13 patients who underwent ejuno-ileal shunting for extreme obesity. Blood amples were taken before and immediately after urgery, and then at 2, 4, 6, 8, 12, 18 and 24 hr fter surgery. A rapid rise in the S-OCT occurred nd was observed at its peak between 2 and 8 hr after he operation. In four patients operated on for inestinal diseases, much smaller rises in the S-OCT ere noted. In a control group of six patients perated on for knee injuries, no changes of the -OCT were noted after operation. The rise in the -OCT is interpreted as a sign of liver cell damage f unknown cause in the patients with jejuno-ileal hunting.

1151 EFFECTS OF ORAL VERSUS INTRAVENOUS NUTRITION ON INTESTINAL ADAPTATION AFTER SMALL BOWEL RESECTION IN THE DOG. (Eng.) Feldman, E. J.; Dowling, R. H.; McNaughton, J.; Peters, T. J. (Royal Postgraduate Medical Sch., London, England). *Gastroenterology* 70(5):712-719; 1976.

The influence of luminal nutrition on the structural and functional adaptive changes in the residual intestine, after partial small bowel resection, was studied. Quantitative histology, *in vitro* uptake of ^{14}C *l*-leucine, mucosal enzyme activities, and *in vivo* absorption of glucose were studied before and 6 weeks after 50% proximal small bowel resection in 10 greyhound dogs (5 were nourished i.v. and 5 were pair-fed by mouth). In the p.o. fed jejunectomized dogs, the ileum became dilated with mucosal hyperplasia, the villus height increased from 796 µm to 1102 µm, and there was a corresponding increase in glucose absorption *in vivo* from 5.3 to 10.1. The increased absorption was apparently caused by the dilation and villus hyperplasia, since there was no significant change in *in vitro* absorption and mucosal enzyme activity when expressed per unit weight of intestine. In the absence of exogenous luminal nutrition, the well nourished i.v. fed dogs showed no evidence of functional adaptation and a significant fall in mean ileal villus height from 823 µm at the initial operation to 732 µm 6 weeks after jejunectomy. These results provide evidence that luminal nutrition is essential for the development of intestinal adaptation after resection and suggest that luminal contents are necessary to maintain the structural and functional integrity of the normal small bowel.

1152 STUDIES ON SMALL INTESTINAL OBSTRUCTION. VI. BLOOD CIRCULATION IN MODERATELY DISTENDED SMALL BOWEL AFTER OBSTRUCTION. (Eng.) Ohman, U. (Karolinska Sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 141(8):771-779; 1975.

Feline small bowel circulation was studied during *in vitro* homologous perfusion of denervated intestine after *in vivo* obstruction. The bowel specimens showed delayed compliance and, when compared with nonobstructed specimens, they showed enhanced distensibility. Bowel specimens investigated during continuous distension had a normal regional vascular resistance and a normal capillary filtration coefficient (CFC) but a somewhat decreased oxygen utilization; artificial distension to 20 mm HG caused a resistance enhancement and a profound (80-90%) reduction of CFC but did not prevent oxygen consumption from attaining normal levels. Bowel specimens investigated after intra-operative decompression showed normal vascular resistance, normal CFC, and normal oxygen consumption; artificial distension to 20 mm Hg produced a resistance enhancement and a moderate (40-50%) reduction of CFC; oxygen consumption was not affected. After release of the distension, flow reduction and resistance enhancement persisted, whereas CFC returned to basal values in both groups of specimens; oxygen consumption remained on stable levels. It is emphasized that the persisting augmentation of resistance observed after decompression of the bowel was re-

LIBRARY U. OF I. URBANA-CHAMPAIGN

lated to the *in vitro* situation, whereas *in vivo* intra-operative decompression of obstructed bowel seemed to involve no consequences of this kind. Some experiments demonstrated fluid output to the gut lumen in the postdistension period. It is concluded that a simple small bowel obstruction, although not involving any serious threat to the bowel viability, renders the gut wall vulnerable to any further increment of distension or ischemia. It is suggested that this is mainly the result of enhanced distensibility in the wall of the obstructed gut.

1153 STUDIES ON SMALL INTESTINAL OBSTRUCTION. V. BLOOD CIRCULATION IN MODERATELY DISTENDED SMALL BOWEL. (Eng.) Ohman, U. (Karolinska Sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 141(8):763-770; 1975.

Feline small bowel circulation was studied for a 60-min period during *in vitro* homologous perfusion of denervated intestine, upon artificial distension to 20 mm Hg. Delayed compliance was observed, and distension evoked contractile bowel activity; each bowel contraction was accompanied by a decrease in blood flow rate, whereas bowel relaxations coincided with augmentations of flow. Artificial distension diminished blood flow, denoting a 50-60% increase of regional vascular resistance. Artificial distension elicited variable capillary filtration coefficient (CFC) responses (on the average a 45-50% reduction of the perfused capillary surface area), but it did not affect the oxygen consumption rate. After release of the distension, the enhancement of vascular resistance persisted and even increased, whereas CFC returned to control level. Control experiments involving homologous perfusion but no artificial distension also demonstrated some resistance augmentation and CFC reduction. Although the experimental procedure may occasion some degree of hemodynamic impairment, the present observations and previous reports suggest that bowel viability is not significantly affected. It is concluded that a sustained and moderate distension of non-obstructed feline small bowel, perfused *in vitro*, involves no threat to the microcirculation or to the viability of the bowel.

1154 ESOPHAGEAL MOTOR DYSFUNCTION IN IDIOPATHIC INTESTINAL PSEUDOOBSTRUCTION. (Eng.) Schuffler, M. D.; Pope, C. E., II. (Univ. Washington Sch. Medicine, Seattle, WA). *Gastroenterology* 70(5):677-682; 1976.

Five patients with idiopathic intestinal pseudo-obstruction (IIP) were studied with esophageal manometry to determine if the esophagus is commonly involved in IIP. All patients had abnormalities of esophageal motility. In two, primary peristalsis was replaced by simultaneous contractions; repetitive spontaneous activity was marked. The lower esophageal sphincter failed to relax and the Mecholyl test was positive in both. In the other three, primary peristalsis was absent, low amplitude simultaneous waves followed swallows, no spontaneous activity was present, and defects in lower esophageal sphincter relaxation were found in two. The Mecholyl test was negative in the one patient tested. The results indicate that the esophagus is abnormal in idiopathic intestinal pseudo-obstruction, and may prove useful as an organ for diagnostic study in these patients.

SMALL INTESTINE

Malabsorption

1182 SMALL INTESTINAL BIOPSY IN CHILDHOOD COELIAC DISEASE. (Eng.) Risdon, R. A.; Wadbrook, D. G.; Meinhard, E. A.; Keeling, J. W. (Hosp. Sick Children, Great Ormond St., London WC1N 3JH, England). *Postgrad. Med. J.* 51(600):716-721; 1975.

Small intestinal biopsies from children with treated and untreated celiac disease were analyzed morphometrically and compared to 37 healthy controls. A total of 113 jejunal biopsies from 90 children (including 30 children with celiac disease) was examined by a technique that provided indices of surface-to-volume ratio and of mucosal volume. Biopsies from 26 untreated celiacs and controls were analyzed by a technique that involves tracing the microscopic image of the biopsy onto computer data cards to produce measured, encoded data for direct computer analysis. Biopsies from untreated celiacs were clearly distinquished from the control specimens by both methods. Computer card morphometry showed that the mucosal lesion in celiac disease was associated with a spatial redistribution of the tissue components rather than a change in their absolute amounts. No difference in total mucosa volume was found, indicating that a true mucosal atrophy does not occur in celiac disease. Surface-to-volume ratios were measured before and after gluten challenge in 23 children treated empirically with a gluten-free diet for 2 yr for suspected celiac disease. The diagnosis of celiac disease was confirmed in 16 of these patients. In morphologically normal biopsies, correlation of surface-to-volume ratios with age showed significantly smaller values in younger children. It is concluded that slight changes in biopsies from young children should be interpreted cautiously and should not necessarily be regarded as pathological on the evidence of the villous pattern alone.

1183 THE COEXISTENCE OF CYSTIC FIBROSIS AND CELIAC DISEASE. (Eng.) Katz, A. J.; Falchuk, Z. M.; Shwachman, H. (Harvard Medical Sch., 300 Longwood Ave., Boston, MA 02115). *Pediatrics* 57(5):715-721; 1976.

Studies were undertaken to determine whether duodenal mucosa obtained from each of two patients with cystic fibrosis (CF) who subsequently developed celiac disease (CD) and their immediate families differed in organ culture behavior from mucosa obtained from patients with CD alone. In addition, HL-A typing was used to determine whether the two patients with CF-CD differed genetically from patients with CD alone. One patient was HL-A8, the most common type associated with CD; the other was HL-A12, as are many of the non-HL-A8 celiac patients. The response in organ culture of the mucosa of these two patients was the same as the response in organ culture of the mucosa from patients with CD alone. These and previous data suggest that CD occurring in patients with CF is no different than CD occurring alone.

1184 MESENTERIC ANGIOGRAPHY OF NON-TROPICAL SPRUE. (Eng.) Cynn, W. -S.; Herasme, V. M.; Levin, B. L.; Gureghian, P. A.; Schreiber, M. N. (Graduate Hosp. Univ. Pennsylvania, Philadelphia, PA 19146). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(2):442-446; 1975.

Mesenteric angiographic findings in two men with nontropical sprue are presented. Both cases were characterized by dilated superior mesenteric artery and vein, increased, but patchy, blush of the small bowel wall, and early and good opacification of veins. The similarity of these angiographic findings with those found in pharmacoangiography with vasodilators suggests that the diffuse capillary blush of the small bowel may be caused either by vasodilation secondary to the disease itself or to increased demand for blood. An allergic or toxic aspect of nontropical sprue might be responsible for the capillary dilatation. Mesenteric angiography may be helpful for the evaluation of the malabsorption syndrome, especially in cases where it is important to eliminate the possibility of a tumor.

1185 TETANY, MALABSORPTION, AND MASTOCYTOSIS. (Eng.) Dantzig, P. I. (Albany Medical Center, Albany, NY 12208). *Arch. Intern. Med.* 135(11):1514-1518; 1975.

Two patients, a 44-yr-old and a 20-yr-old woman, with systemic mastocytosis, tetany, and malabsorption were studied during periods of diarrhea and normal gastrointestinal function to determine the nature of the malabsorption and tetany. Both patients had symptoms of pruritus, flushing, tachycardia, diarrhea, weakness, and abdominal pain. Laboratory tests revealed flat glucose and lactose tolerance curves, low D-xylose absorption, low serum carotene, low serum calcium, and low serum iron levels when the patients were studied without diarrhea. These tests suggested abnormal jejunal functions. Serum magnesium and protrombin time levels used as a measure of vitamin K absorption, were normal between bouts of diarrhea. A Schilling test in each patient was normal, indicating at least partial retainment of absorptive function. All indicators of absorption, including electrolytes, minerals, fats, proteins, and vitamins worsened with diarrhea. Small intestinal biopsies showed infiltration of the lamina propria and submucosa by mast cells, and gastrointestinal x-ray films showed nodular densities, edema, and thickening of the intestinal wall. Tetany was due in part to combined hypocalcemia, hypomagnesemia, and hypokalemia. Diarrhea and malabsorption were due to mast cell infiltration of the small intestine rather than to histamine. It is concluded that patients with signs of systemic mastocytosis should be followed carefully to prevent the development of malabsorption and tetany.

1204 ADENOVIRUS AND ILEOCECAL INTUSSUSCEPTION.

(Eng.) Yunis, E. J.; Atchison, R. W.; Michaels, R. H.; DeCicco, F. A. (Dept. Pathology, Univ. Pittsburgh, Pittsburgh, PA 15213). *Lab. Invest.* 33(4):347-351; 1975.

Tissue slides from 682 appendices removed from children operated on for ileocecal intussusception over a 4-yr period were examined retrospectively and prospectively by light and electron microscopy for the presence of adenovirus infection. Intranuclear inclusion bodies were found by light microscopy in epithelial cells in more than one-third of the specimens. Electron microscopy of hematoxylin and eosin-stained slides showed the intranuclear inclusion bodies to be composed of viral particles in large and small crystalline arrays. Adenovirus of serotypes 2, 3, and 5 were isolated from the five cases with inclusion in which isolation was attempted. The electron microscope demonstration of replicating adenovirus in appendiceal mucosa in 11 of 30 cases suggests a pathogenic role for adenovirus in those cases of intussusception in which intranuclear inclusion bodies are found in the epithelial cells of the appendix or terminal ileum.

1205 THE COLITIS OF BEHCET'S DISEASE: A CLINICAL-RADIOGRAPHIC CORRELATION.

(Eng.) Stanley, R. J.; Tedesco, F. J.; Melson, G. L.; Geisse, G.; Herold, S. L. (Washington Univ. Sch. Medicine, 510 S. Kingshighway, St. Louis, MO 63110). *Radiology* 114(3):603-604; 1975.

The radiographic, colonoscopic, and pathologic findings of colitis associated with Behcet's disease in a 34-yr-old woman are presented. The patient presenting with a 3-yr history of Behcet's disease developed profuse rectal bleeding on three occasions, which was only partially responsive to vasopressin; right colectomy was performed on the first occasion, and the remainder of the colon to the distal sigmoid was resected on the third occasion. Multiple discrete ulcers were present in the resected portions of colon. No tortuous arterioles, mucosal hyperemia, or early venous filling were encountered, using superior mesenteric arteriography. The results suggest that the radiographic and colonoscopic features of the colonic involvement in Behcet's disease may be quite specific when they are associated with other clinical manifestations of the disease. Radiographic discovery of multiple, well marginated ulcers similar to duodenal or gastric ulcers in an otherwise unremarkable-appearing colon should lead to inquiry concerning the presence of oral or genital ulcers or occular inflammatory disease.

1206 ISCHEMIC COLITIS AFTER ABDOMINOPERINEAL RESECTION.

(Eng.) Wittenberg, J.; O'Sullivan, P.; Williams, L., Jr. (Boston City Hosp., Boston Univ. Medical Center, Boston, MA). *Gastroenterology* 69(6):1321-1325; 1975.

Four cases of ischemic colitis occurring at intervals from 3 months to 7 yr after abdominoperineal resection for carcinoma of the distal colon are described. In three of the four patients, the predominant blood supply to the affected segment of colon was via the middle colic branch of the superior mesenteric artery, despite the presence of the inferior mesenteric artery. The lack of collateral circulation provided by the resected colon probably increases the risk of developing ischemic colitis in the remaining colon. The sparing of the distal colon and colostomy site in the four patients was paradoxical. A possible explanation is that collateral channels, not derived from the mesenteric circulation, were available. The authors hypothesize that during the ischemic attack, the vascular insult selectively affects the mesenteric arterial circulation and that the systemic circulation remains available for collateral flow to the distal colon.

1207 ANALYSIS OF CECAL VASCULATURE IN THE SEARCH FOR VASCULAR MALFORMATIONS.

(Eng.) Baer, J. W.; Ryan, S. (St. Luke's Hosp. Center, New York, NY). *Am. J. Roentgenol.* 126(2):394-405; 1976.

Four cases of vascular malformation of the cecum resulting in gastrointestinal bleeding, diagnosed angiographically, are described. In addition, the angiographic findings of 39 normal cecum specimens and the microscopic features of 26 normal postmortem cecum specimens were studied to establish the angioarchitecture of the cecum and to define the anatomy of the antimesenteric border where the majority of vascular malformations occur. The control study of autopsy and surgical specimens revealed that there was a 1:1 ratio of artery to vein at the antimesenteric border. There were many anastomoses along the mesenteric border between the vasa recta of opposite walls of the colon. Longitudinal anastomoses between parallel vasa recta distal to the antimesenteric taeniae ensure continuous perfusion of the bowel during peristalsis. Thus, vascular occlusion must occur on the small arteries of the submucosa or within the mesentery to produce ischemia of the bowel. Therefore, the anatomical venous changes observed in vascular malformations of the cecum can be acquired. The authors postulate that vascular malformations are the result of functional shunting. Barium enema examinations were negative in all four cases. In three of the four, early venous filling identified the cecal vascular malformation. The histologic appearance of these lesions was similar to the venous ectasia of acute localized hyperemia of bleeding diverticula and generalized venous engorgement associated with increased venous pressure. The authors conclude that diagnosis of vascular malformations of the cecum and ascending colon should be strongly suspected in patients between 40-85 yr of age presenting with chronic intermittent bleeding from the lower gastrointestinal tract together with a negative barium examination.

1208 MANOMETRIC ASSESSMENT OF CONTINENCE AFTER SURGERY FOR IMPERFORATE ANUS.

(Eng.) Arhan, P.; Faverdin, C.; Devroede, G.; Dubois, F.; Coupris, L.; Pellerin, D. (Faculte Necker-Enfants-

Malades, 156, Rue de Vaugirard, 75015, Paris, France). *J. Pediatr. Surg.* 11(2):157-166; 1976.

Rectal and anal sphincteric resting pressures were studied in 49 children at least 1 yr following surgery for imperforate anus. Twenty-three children underwent an abdominoperineal procedure for a high and 7 for a low malformation; 17 had a perineoplasty for a low and 2 for a high malformation. Of the 30 subjects who underwent an abdominoperineal procedure, 8 were continent in contrast to 15 out of 19 patients who had perineoplasty ($p<0.001$). In patients who underwent an abdominoperineal procedure, the rectal motility was of the colonic type, with waves of higher amplitude and lower frequency ($p<0.01$) than in the normal rectum in 23 cases and in most of these, peristalsis was recorded down to the anal margin. Incontinence was most frequently associated with abnormally short anal resistance, low anal pressure, reduced sensibility, weak voluntary contraction, and absence of recto-anal inhibitory reflex. In the group of patients who underwent perineoplasy, continence was associated with normal mechanical parameters and normal physiologic behavior of the anal sphincter.

1209 THE DEVELOPMENT OF ANORECTAL CONTINENCE AND ITS SIGNIFICANCE IN THE DIAGNOSIS OF HIRSCHSPRUNG'S DISEASE. (Eng.) Holschneider, A. M.; Kellner, E.; Streibl, P.; Sippell, W. G. (Universitats-Kinderklinik, Lindwurmstrasse 4, D-8000 Munchen 2, W. Germany). *J. Pediatr. Surg.* 11(2):151-156; 1976.

The development of the anorectal continence reaction was studied in a series of 138 electromanometric recordings performed in 62 newborn and 6 premature infants. In 11% of 45 infants observed in a longitudinal study, an internal sphincter relaxation was observed at the time of birth. The same reflex was present in about 50%, after the third day, and in all infants after the 12th day of life. After direct volume stimulation with 0.1-0.2 ml of water, a normal reflex contraction of the puborectalis muscle was recorded in all investigated infants, regardless of age. The continence reflex, however, (i.e., a reflex puborectalis contraction after an internal sphincter relaxation) developed according to the delayed maturation of the internal sphincter reflex. The results indicate that electromanometric recordings can be used to exclude aganglionic megacolon as early as the first day of life. An absent internal sphincter relaxation reflex is diagnostic only after the 12th day of life.

LARGE INTESTINE

Ulcerative Colitis

1252 TREATMENT OF ULCERATIVE COLITIS WITH ORAL DISODIUM CROMOGLYCATE: A DOUBLE-BLIND CONTROLLED TRIAL. (Eng.) Mani, V.; Green, F. H. Y.; Lloyd, G.; Fox, H.; Turnberg, L. A. (Manchester Royal Infirmary, Manchester, England). *Lancet* 1(7957):439-441; 1976.

Twelve patients with ulcerative proctocolitis were treated for 6 months with each of p.o. disodium cromoglycate (2 g/day) and placebo in a double-blind crossover trial. The active drug significantly improved the patients' sense of well-being and the sigmoidoscopic and rectal biopsy appearances. Side effects were minor (nausea, rash, and bitter taste), and they disappeared without withdrawal of the drug. Therapy was discontinued in two patients developing elevated serum transaminase levels. The authors conclude that the p.o. administration of disodium cromoglycate may have a place in the long term management of ulcerative proctocolitis since inflammatory changes in the bowel appear to be favorably influenced.

1253 IMMUNOSUPPRESSION IN THE TREATMENT OF INFLAMMATORY BOWEL DISEASE: II. THE EFFECTS OF AZATHIOPRINE ON LYMPHOID CELL POPULATIONS IN A DOUBLE BLIND TRIAL IN ULCERATIVE COLITIS. (Eng.) Campbell, A. C.; Skinner, J. M.; Maclennan, I. C. M.; Hersey, P.; Waller, C. A.; Wood, J.; Jewell, D. P.; Truelove, S. C. (Swiss Inst. Experimental Cancer Res., 1011 Lausanne, Switzerland). *Clin. Exp. Immunol.* 24(2):249-258; 1976.

Blood lymphocytes and rectal plasma cells were studied in 26 patients with ulcerative colitis to evaluate the effect of treatment with azathioprine. Treatment for 1 yr (2.5 mg/kg/day) resulted in a modest decrease in lymphocyte count, with little change in neutrophils or platelets. There was no major change in the proportions of circulating T and B lymphocytes, suggesting that the number of such cells per milliliter of blood fell in proportion to the change in lymphocyte count. The number of plasma cells in the rectal lamina propria was

LIBRARY U. OF I.

reduced to a mean less than half that of the control patient group. Blood antibody-dependent lymphocyte-mediated cytotoxicity (K-cell activity) fell at least 25-fold after 1 yr treatment. Phytohemagglutinin-induced cytotoxicity was also reduced, but less consistently. Reduced K-cell activity is interpreted as reflecting depletion of effector cells from the circulation. The fall in lymphocyte count, K-cell activity, and gut plasma cells was slow, indicating continuous inhibition of lymphopoiesis or differentiation throughout the trial period. Thus, azathioprine administration results in some immunosuppressive effects that develop only after prolonged treatment. The clinical results of the trial did not show that azathioprine had a major beneficial effect in the treatment of ulcerative colitis, nor were there clear correlations between the results of lymphocyte assays and clinical response in individual patients.

1254 ILEORECTAL ANASTOMOSIS IN ULCERATIVE COLITIS: RESULTS IN 57 PATIENTS. (Eng.) Gruner, O. P. N.; Flatmark, A.; Naas, R.; Fretheim, B.; Gjone, E. (Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(6):641-646; 1975.

The results of ileorectal anastomosis (IRA) were evaluated in 57 patients with ulcerative colitis. The operative mortality was 7% in all cases and 10.5% in fulminating cases. Of 48 patients who were initially discharged from the hospital with IRA, 3 developed cancer of the rectal stump. Half of all surviving patients needed rectal extirpation and ileostomy because of rectal dysfunction. Rectal function, stenosis, and inflammation were significantly worse in women than in men. Dyspareunia was experienced in 8 of 15 women with IRA. The authors suggest that the use of IRA in the treatment of ulcerative colitis may not be justified due to the increased risk of developing rectal cancer.

PANCREAS

Pancreatitis

1281 GASTRIC INHIBITORY POLYPEPTIDE (GIP) IN CHRONIC PANCREATITIS. (Eng.) Botha, J. L.; Vinik, A. I.; Brown, J. C. (Endocrine and Diabetes Research Unit, Univ. Cape Town, Cape Town, South Africa). *J. Clin. Endocrinol. Metab.* 42(5):791-797; 1976.

Gastric inhibitory polypeptide (GIP) responses to the ingestion of glucose were studied in five male patients with chronic pancreatitis and in five control subjects. After an overnight fast, an indwelling cannula was inserted into an antecubital vein for blood sampling. After taking three basal samples, 50 g glucose in 150 ml water was ingested and additional blood samples were drawn at 1, 3, 5, 10, 20, 30, 60, 90, and 120 min thereafter. Both the mean blood glucose levels and the response to glucose ingestion were significantly higher, at all times, in the patients than in the controls. Following glucose ingestion, there was a rapid rise in circulating GIP before the rise in circulating insulin or glucose concentrations. The rise in GIP concentration was significant at 10 min in patients and at 20 min in controls. The GIP levels were significantly higher in patients at 10, 20, and 30 min after ingestion of glucose. The mean fasting plasma insulin levels were similar in patients and in controls. After ingestion of glucose, there was a more rapid and significantly higher rise in insulin concentration in controls at 20 and at 30 min, but the mean peak concentrations were not significantly different. The mean fasting plasma pancreatic glucagon-like immunoreactivity (PGLI) levels in patients were higher than in controls. After ingestion of glucose, there was an apparent but insignificant rise within the first 5 min in both patients and controls. These levels were maintained in patients and were significantly higher than in the controls at 10, 20, and 60 min after ingestion. The mean fasting plasma gut glucagon-like immunoreactivity (GGLI) levels in patients were higher. Following glucose ingestion, a sharp early rise occurred in the patients' levels, reminiscent of the GIP response and the 5 and 10 min levels were significantly higher than in controls who were not significantly affected by glucose. These findings confirm earlier reports that oral glucose stimulates the release of GIP from the gastrointestinal tract in normals. A further similarity between pancreatic and genetic diabetes, namely the hypersecretion of GIP, was also demonstrated.

1282 PROSTAGLANDIN RELEASE IN CANINE ACUTE HAEMORRHAGIC PANCREATITIS. (Eng.) Glazer, G.; Bennett, A. (St. Mary's Hosp. Medical Sch., London, England). *Gut* 17(1):22-26; 1976.

The prostaglandin (PG)-like activity in dog pancreatic venous blood, the general circulation, and the peritoneal exudate after the induction of acute hemorrhagic pancreatitis (AHP) were measured in adult greyhound dogs following a bile salt/trypsin injection into the main pancreatic duct. All dogs showed the macroscopic changes of edema, congestion, and hemorrhagic areas in the pancreas together with a serosanguinous peritoneal exudate. They demonstrated an acute transitory fall in blood pressure (BP) during the infusion of the bile salt/trypsin mixture. The BP fell steadily throughout the experiment from a mean basal of 155 mmHg to 75 mmHg at 3 hr following the injection. Blood amylase rose. Hemoconcentration occurred, as reflected in the rising hematocrit. The level of PG-like material in the pancreatic venous blood of dogs with AHP rose steadily from a mean average basal level of 0.3 ng/ml PGE_2 equivalents to 1.0 ng/ml at 30 minutes and 1.7 ng/ml at 3 hr. The levels in mixed venous blood did not change significantly in either the treated or the control group, and although the mean level of PG-like material in th arterial blood of dogs with AHP was higher than in controls, this did not reach statistical significance. Large amounts of PG-like material occurred in the peritoneal exudates from dogs with AHP (43 ng/ml PGE_2 equivalents). Chromatographic analysis and susceptibility to alkaline hydrolysis indicated a PGE compound with traces of other activity in some samples. Results indicate that during the early stages of AHP in the dog, PG-like material is released into the pancreatic venous blood. The peritoneal exudate contains substantial PG-like activity as well. As pancreatic vasoconstriction during acute pancreatitis increases tissue anoxia and acinar cell damage and eventually causes gland necrosis, local vascular effects of PG's may be important. It is concluded that prostaglandins contributed to the induced pancreatitis.

1283 ACUTE HEMORRHAGIC PANCREATIC NECROSIS IN MICE. INTRAPARENCHYMAL ACTIVATION OF ZYMOGENS, AND OTHER ENZYME CHANGES IN PANCREAS AND SERUM. (Eng.) Rao, K. N.; Tuma, J.; Lombardi, B. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *Gastroenterology* 70(5):720-726; 1976.

The relation between intraparenchymal activation of the proteolytic zymogens of the pancreas and acute hemorrhagic pancreatic necrosis (AHPN) was studied in 30 day old female Swiss Webster mice fed a choline-deficient diet supplemented with 0.5% DL-ethionine. The diet caused two major changes in the pancreas: a marked increase in the weight and protein content of the organ, and the appearance in the gland of substantial amounts of active pancreatic proteases. The increases in weight and protein were sustained by increased contents of zymogens and amylase. This accumulation of zymogens is one of the earliest characteristics of the process. It may also be critical in the development of AHPN, as it leads to the presence in the acinar cells of abnormally high quantities of dangerous materials. After 2 and 3 day of feeding, 70-90% of the elastolytic activity was present as elastase, whereas trypsin and chymotrypsin constituted only a small fraction of the trypsinogen and chymotrypsinogen contents. These findings indicate that the endogenous buffering capacity of the pancreas was overcome. The decline of α_1-antitrypsin and of α_2-macroglobulin from the first to the third day of treatment indicates that active pancreatic proteases were transferred into the circulation and reacted with the inhibitors, thus decreasing their blood levels. The results indicate that input of trypsin or of other pancreatic enzymes into the circulation is the triggering factor in the onset of the deep shock-like state that precedes the death of the mice with AHPN. Proteases and lipases, transferred via the circulation or spilled into the peritoneal cavity, may account for the diffuse necrosis of the peritoneal fat tissues that accompanies pancreatitis.

1299 α_1-ANTITRYPSIN DEFICIENCY AND LIVER DISEASE IN CHILDREN.

(Eng.) Burke, J. A.; Kiesel, J. L.; Blair, J. D. (Univ. Kentucky Medical Center, Lexington, KY 40506). *Am. J. Dis. Child.* 130(6):621-629; 1976.

The clinical, biochemical, and hepatic morphologic findings in 10 children with severe serum α_1-antitrypsin deficiency are presented. Genetic protease inhibitor (Pi) phenotyping, using acid-starch gel and crossed antigen-antibody electrophoresis, demonstrated Pi phenotype ZZ in all cases. In eight patients, manifestations of liver disease appeared during the first year of life. The case reports show that α_1-antitrypsin deficiency should be suspected in any child with neonatal hepatitis, unexplained hepatomegaly or splenomegaly, or cirrhosis. One of the reported infants was normal at age 6 months, and one infant had progressive hepatic damage that culminated in liver failure and death at age 6 months. The variable clinical course and prognosis for infants with severe α_1-antitrypsin deficiency is well illustrated by these two infants.

1300 COMPLEMENT STUDIES IN ALPHA-1-ANTITRYPSIN DEFICIENCY IN CHILDREN.

(Eng.) Le Prevost, C.; Frommel, D.; Dupuy, J. -M. (U-56 INSERM, Hopital d'Enfants, Bicetre, France). *J. Pediatr.* 87(4):571-573; 1975.

The complement system of 18 children with alpha-1-antitrypsin deficiency associated with liver disease was studied to determine the consequence of the lack of a major antiprotease. Component 4 (C4) was the only component displaying decreased values, with an average hemolytic titer of 32% (range, 5-60%) and an average immunochemical titer of 42% (range, 5-68%). C4 hemolytic values determined in 31 controls appeared normal (100-113%). Components C1-C9, C1q, C1s, and C3PA were all normal. Prospective studies including sequential determinations of C4 related to the clinical evolution of liver disease may be valuable.

1301 THE DISPARITY OF THE SIZE OF THE LIVER AS DETERMINED BY PHYSICAL EXAMINATION AND BY HEPATIC GAMMASCANNING IN 504 PATIENTS.

(Eng.) Ariel, I. M.; Briceno, M. (Pack Medical Foundation, 137 E. 36th St., New York, NY 10016). *Med. Pediatr. Oncol.* 2(1):69-73; 1976.

The extent that the liver extended inferior to the costal margin as determined by physical examination (palpation, percussion, and after deep inspiration) in 504 patients was compared to the size determined by hepatic gammascanning. Scanning was performed using ^{131}I rose bengal, radioactive gold, or ^{99m}technetium sulfur colloid. Hepatic gammascanning revealed that the liver extended inferior to the costal margin a minimum of 5 cm in 259 of the 504 patients. However, physical examination revealed a palpable liver in only 123 patients. This study demonstrates that physical examination by palpation is not a good index for determining hepatomegaly.

1302 INCREASED SULFOBROMOPHTHALEIN CLEARANCE IN A PATIENT RECEIVING PHENOBARBITAL AND OTHER ANTICONVULSANT DRUGS.

(Eng.) Capron, J. P.; Erlinger, S.; Feldmann, G. (Unite de Recherches de Physiopathologie Hepatique, Hopital Beaujon, 92110 Clichy, France). *Gastroenterology* 69(3):756-760; 1976.

A marked enhancement in the plasma disappearance rate of BSP, along with signs of hepatic microsomal enzyme induction, are reported in a 43-yr-old man who was taking anticonvulsant drugs. He received phenobarbital from the age of 13 yr (0.20-0.40 g/day), diphenylhydantoin for a 5-yr period (0.20 g/day), primadone (0.75 g/day), and clonazepam (0.004 g/day) for 2 yr previous to the study. There was a marked increase in the fractional clearance rates of BSP, dibromosulfophthalein, and indocyanine green in comparison to normal standards. This was related to a marked increase in hepatic blood flow, while hepatic extraction remained normal. There was an associated twofold increase in liver bilirubin UDP-glucuronyltransferase activity and hypertrophy of the smooth endoplasmic reticulum in the hepatocytes. It is concluded that drug administration (especially phenobarbital) should be considered as a possible cause of increased BSP clearance in man.

1303 NUCLEOTIDE PYROPHOSPHATASE AND PHOSPHODIESTERASE I. DEMONSTRATION OF ACTIVITY IN NORMAL SERUM, AND AN INCREASE IN CHOLESTATIC LIVER DISEASE.

(Eng.) Haugen, H. F.; Skrede, S. (Inst. Clinical Biochemistry, Univ. Oslo, Oslo 1, Norway). *Scand. J. Gastroenterol.* 11(2):121-127; 1976.

The presence of nucleotide pyrophosphatase/phosphodiesterase I in normal sera, and its increase in liver disease were investigated in 10 normal, nonfasting blood donors and in patients diagnosed as having acute hepatitis (11), active chronic hepatitis (21), primary biliary cirrhosis (14), and malignant bone lesions (5). Nucleotide pyrophosphate was present in normal human serum. Also thymidine-5'-monophospho-nitrophenyl ester was hydrolyzed in normal human serum, with a K_m of about 0.20-0.25 mM. The pH-optimum of phosphodiesterase activity was very close t or identical with the optimum of nucleotide pyrophosphatase, about 9.8. Contrary to expectations, 3M urea inhibited alkaline phosphatases in sera from patients with liver disease or bone lesions completely whereas phosphodiesterase I was only moderately inhibited. Uridine diphosphoglucose (UDPH, 1 mM) did not inhibit alkaline phosphatases, but it did cause a marked inhibition of phosphodiesterase I by a competitive pattern. The extent of phosphodiesterase I inhibition by urea was not different in sera from normal individuals, pregnant women, and from patients with liver diseases or bone lesions. Total, as well as urea-inhibited phosphodiesterase I activity, was increased in normal pregnancy and in bone lesions. In both acute viral hepatitis and active chronic hepatitis, a slight increase was noted in a few cases (about 20%), whereas 80% of the patients with primary biliary cirrhosis had increased levels. Levels of phosphodiesterase I and nucleotide pyrophosphatase were significantly higher in primary biliary cirrhosis than in active chronic hepatitis. It is suggested tha further studies are necessary to evaluate the diagnostic role of nucleotide pyrophosphatase/phosphodiesterase I.

1304 BILE CANALICULAR ALKALINE PHOSPHATASE IN NECROPSY SPECIMENS OF THE LIVER AND ITS RELATION TO DISEASE.

(Eng.) Hagerstrand, I. (General Hosp., Malmo, Sweden). *Acta Pathol. Microbiol. Scand.* [*A*] 84(3):278-284; 1976.

The frequency of canalicular alkaline phosphatase activity from 185 consecutive autopsies, its relation to the patient's disease, and a comparison with diseases of subjects without such activity was investigated. Of all the subjects with malignant tumors and liver involvement, 77% had canalicular alkaline phosphatase. No correlation was found between the type or extent of the tumor and the presence or absence of canalicular alkaline phosphatase. However, metastases to the liver and lungs were found less frequently in subjects with a normal sinusoidal hepatic reaction. An assumed connection between the canalicular enzyme activity and the Pi Z gene was not demonstrated. Centrolobular hepatic necroses were associated with alkaline phosphatase activity of the bile canaliculi in the remaining parenchyma. Any association between use of drugs or alcohol abuse and the occurrence of canalicular alkaline phosphatase was not demonstrated. No correlation was noted between total serum alkaline phosphatase and the histochemical pattern of the enzyme in the liver. It is concluded that isolated canalicular increase of alkaline phosphatase reaction is the common pattern of collagen diseases and centrolobular hepatic necroses, while tumor diseases without involvement of the liver might show both an isolated canalicular increase and a combined canalicular and sinusoidal increase.

1305 PRIMARY FIBROSARCOMA OF THE LIVER: CASE REPORT AND REVIEW OF THE LITERATURE.

(Eng.) Alrenga, D. P. (Cook County Hosp., 1825 W. Harrison St., Chicago, IL 60612). *Cancer* 36(2): 446-449; 1975.

A case of primary fibrosarcoma of the liver associated with cirrhosis occurring in a 51-yr-old man is presented. The patient had no history of alcoholism, hepatitis, or exposure to any hepatotoxic substances, but suffered a 30-lb weight loss, prior to hospitalization. At autopsy, the tumor was 17 cm in diameter and was observed to invade the portal vein. No metastases were found. Fifteen additional cases of this unusual neoplasm are reviewed.

1306 ELECTRON MICROSCOPIC OBSERVATION OF THE LIVER IN CHILDREN WITH HURLER'S SYNDROME.

(Jpn.) Horino, K.; Orii, T.; Denpo, K. (Sapporo Medical Coll., Sapporo, Japan). *Nihon Rynsho Denshi Kenbikyo Gakkai-Shi* 7(1):73-82; 1974.

Liver specimens from two boys (biopsy, 5-yr-old; autopsy, 13-yr-old) with Hurler's syndrome were studied by electron microscopy, and compared to other cases of mucopolysaccharidosis and mucolipidosis. Numerous storage vacuoles, implying typical accumulation of mucopolysaccarides, were found in the cytoplasm of hepatocytes and sinusoidal cells. In the hepatocyte vacuoles, fine reticula were scattered, and near the limiting membranes, electron dense granules, vesicles, and myelin-like structures were found. Absence of normal peribiliary dense bodies (lysosomes) indicated that storage vacuoles arose from lysosomes. Many mitochondria exhibited budding phenomena. These buds (0.1-0.2 μm in size) separated from the mitochondria, and were converted to vesicles near the mitochondria. Vacuoles that were smaller than those found in hepatocytes (0.5-10.0 μm) were found in the sinusoidal cells (0.5-1.5 μm). Sinusoidal cell vacuoles were relatively electron lucid; vesicles and electron dense granules were not present. Cellular debris and vacuoles were scattered in the sinusoids. In general, abnormal storage patterns were found in the epithelial cells for mucopolysaccharidoses and in the interlobar cells for mucolipidoses.

1307 NODULAR REGENERATIVE HYPERPLASIA OF THE LIVER.

(Eng.) Knowles, D. M., II; Kaye, G. I.; Godman, G. C. (Coll. Physicians and Surgeons, Columbia Univ., 630 W. 168 St., New York, NY 10032). *Gastroenterology* 69(3):746-751; 1975.

A case of nodular regenerative hyperplasia of the liver in a 42-yr-old man is reported and 19 apparent cases in the English literature are reviewed. When examined, the patient was found to have abnormal liver function tests. He later developed episodic shaking chills, fever, and hepatosplenomegaly. Laparotomy and liver biopsy were negative, and the man was discharged without diagnosis. At laparotomy, a wedge section of the liver was taken and the spleen was removed. The liver specimen was misinterpreted as diffuse, well-differentiated hepatoma, and chronic passive splenic congestion was observed. Postoperatively the patient suffered from several episodes of sudden transient confusion and lethargy, and intermittent fever continued. 5-Fluorouracil therapy was begun, but the patient died 5 days later. At autopsy, the liver was covered with many closely spaced 1-4 cm nodules, microscopically identified as circumscribed collections of normal appearing hepatocytes without bile ducts or central veins. Of the cases reported in the literature, six patients had Felty's syndrome and 12 had congestive heart failure. Splenomegaly, the absence of jaundice and stigmata of chronic liver disease, and generally normal liver function tests seem to be common characteristics. The elucidation of the pathogenesis and natural history of this disease requires further investigation.

1308 ABNORMALITIES OF CARBAMYL PHOSPHATE SYNTHETASE AND ORNITHINE TRANSCARBAMYLASE IN LIVER OF PATIENTS WITH REYE'S SYNDROME.

(Eng.) Sinatra, F.; Yoshida, T.; Applebaum, M.; Mason, W.; Hoogenraad, N. J.; Sunshine, P. (Stanford Univ. Sch. Medicine, Stanford, CA). *Pediatr. Res.* 9(11):829-833; 1975.

Urea cycle function was evaluated in liver obtained

LIBRARY U. OF I.

from six patients (2 boys and 4 girls) with Reye's syndrome and from five controls to examine the relationship between Reye's syndrome and defects in urea biosynthesis. The Reye's syndrome patients demonstrated normal activities for the extramitochondrial portion of the urea cycle but showed marked abnormalities of carbamyl phosphate synthetase (CPS) and ornithine transcarbamylase (OTC). CPS activity was reduced to less than 15% of control values in all four patients from whom tissue was obtained during the first 72 hr after the onset of encephalopathy. Two patients from whom tissue was not obtained until after 9 days of symptoms showed no reduction in CPS activity. The OTC activity was also reduced (3-67% of control values) in the four patients from whom tissue was obtained early in the illness. In addition, there was greater than 60% reduction in V_{max} and K_m for carbamyl phosphate in all four patients in whom sample size permitted kinetic analysis, including both patients in whom CPS and OTC activity were not markedly reduced. The same kinetic abnormality as well as decreased CPS activity were experimentally produced in normal rat liver incubated in the presence of 1.0 mM 4-pentenoic acid, a short chain fatty acid and known hepatic mitochondrial toxin.

1309 THE LIVER IN HEREDITARY HEMORRHAGIC TELANGIECTASIA (OSLER-WEBER-RENDU DISEASE). (Eng.)

Daly, J. J.; Schiller, A. L. (Massachusetts General Hosp., Boston, MA 02114). *Am. J. Med.* 60(5):723-726; 1976.

Liver involvement in hereditary hemorrhagic telangiectasia was examined in four patients at autopsy. The gross appearance of the liver varied considerably in each case as did historic data concerning bleeding episodes and transfusion exposure. Hepatomegaly was an inconstant clinical finding and hepatic function was little impaired. Liver disease was evident in all cases. The only consistent findings were at the microscopic level. Three overlapping and apparently interrelated histologic patterns dominated; they incorporated varying degrees of prominence in the number, caliber, and tortuosity of vascular channels and were associated with stromal fibrosis that differed in extent and maturity. The composition of all hepatic lesions was accounted for without implicating other disease processes. Also, stigmata characteristic of complicating conditions such as hepatitis and cirrhosis were not observed. Therefore, these random focal fibrovascular lesions may be examples of various possible manifestations along a spectrum of vascular abnormalities that represent hepatic involvement in hereditary hemorrhagic telangiectasia. Theses lesions are probably slow-developing and are relatively innocuous. The importance of distinguishing between hepatic involvement in hereditary hemorrhagic telangiectasia and the various forms of hepatitis and cirrhosis that tend to complicate the condition is emphasized.

1310 HEPATIC VENO-OCCLUSIVE DISEASE IN A RENAL TRANSPLANT PATIENT RECEIVING AZATHIOPRINE.

(E.) Marubbio, A. T.; Danielson, B. (Hennepin County Medical Center, 5th St. and Portland South, Minneapolis, MN 55415). *Gastroenterology* 69(3):739-743; 1975.

The development of hepatic veno-occlusive disease in a 54-yr-old man receiving azathioprine (Imuran) to prevent rejection of a renal homograft is described. The patient presented in 1967 with nephrotic syndrome, hypertension, and moderately reduced renal function, and was diagnosed as having membranous glomerulonephritis (by renal biopsy). In 1972, he received a related-donor kidney; immunosuppressive therapy included methylprednisolone, azathioprine, and antilymphocyte globulin. One yr after transplantation, SGOT was elevated at 65 Karmen U (normal 10-45 Karmen U/ml). The azathioprine dose was decreased to approximately 1 mg/kg/day; prednisolone was continued at 20 mg/day. Fourteen months after transplantation, mild right upper quadrant pain and jaundice developed; 2 months later the patient was admitted for liver biopsy. On histological examination, the liver showed diffuse mid- and centrilobular congestion. The central veins were surrounded by collagen and showed subintimal edema. Centrally, small canalicular bile plugs were present. Azathioprine therapy was discontinued and cyclophosphamide (Cytoxan) was begun (1.25 mg/kg/day). Clinically, fluid retention and ascites developed without any evidence of cardiac failure, proteinuria, or peritonitis. Examination of tissue from the second biopsy, performed 18 months after transplantation, found a striking increase in the previous finding and collagen completely obliterated some central veins. The patient's clinical course was characterized by persistent low grade fever, worsening ascites, and peripheral edema that necessitated readmission 19 months after transplantation. Physical examination revealed an obviously jaundiced patient with marked muscle wasting. A few days later he developed severe dyspnea, fever, and left sided pulmonary infiltrate and died within 12 hr. Several known causes of veno-occlusive disease and the possible causes in this patient are discussed. Based upon the present experience, it is suggested that a liver biopsy be done in such patients if and when the liver chemistries become deranged. If centrilobular necrosis, hemorrhage or fibrosis are seen, discontinuation of immunosuppressive therapy is indicated.

1311 THE KINETICS OF COPPER UPTAKE BY THE LIVER IN WILSON'S DISEASE STUDIED BY A WHOLE-BODY COUNTER AND A DOUBLE LABELLING TECHNIQUE.

(Eng.) Gunther, K.; Lossner, V.; Lossner, J.; Biesold, D. (Dept. Neurochemistry, Karl Marx Univ., Leipzig, Germany). *Eur. Neurol.* 13(5):385-394; 1975.

The hepatic uptake of ^{64}Cu by a normal female control, two clinically healthy subjects regarded as heterozygotes (44-yr-old male and 60-yr-old female), and two patients with Wilson's disease (18-yr-old man and 23-yr-old woman) was measured using a double labeling technique with ^{64}Cu- and ^{51}Cr-labeled RBC to correct for extracellular copper. Special attention was directed towards copper uptake kinetics during the first hour after injection. Two different measuring techniques were employed simultaneously: one collimated Na(Tl) crystal was in a fixed position over the liver, counts being recorded by a single channel analyzer connected to a multichannel analyzer in a multichannel scaling mode. A second collimated crystal made scanning movements along the body axis, counts being recorded by a multichannel analyzer in a multispectrum scaling mode. Curves showing a rapid increase of total ^{64}Cu values by multichannel scaling were similar for the normal control and a heterozygote. The curve for a patient with Wilson's disease showed only a slight increase. The calculated fractions of copper in the blood and in liver tissue, assuming that the head is not a storage area, gave similar curves for the normal control and the heterozygotes, but a decrease in blood copper content and an increase in liver storage were delayed in the patients with Wilson's disease. The heterozygotes stored 70-90% of the copper in the liver in relation to the blood copper content of the liver region; the normal control stored approximately 50%, and the patients with Wilson's disease stored only 15% and 30%. Thus, the use of a double nuclide labeling technique enabled both ^{64}Cu values for an organ to be corrected for the ^{64}Cu blood content, and provided information on the actual dynamic ^{64}Cu movement in the body.

1312 HEPATIC TRAUMA INVOLVING THE HEPATIC VEINS AND VENA CAVA. (Eng.) McMaster, P. (Addenbrooke's Hosp., Cambridge, England). *Injury* 7(4):299-305; 1976.

Five cases (three children and two adults) of major hepatic injuries with involvement of hepatic veins and inferior vena cava are reported. Only one of these patients survived, but death was probably related more to the extensive associated injuries than to the hepatic and caval injuries alone. Massive transfusion was required in each patient with an average of 22 units of blood for each child and 37 for each adult. Most of this blood was needed and used within the first 2-3 hr after admission. Packs may be used temporarily when major hepatic and caval injury is encountered to allow time for the control of hypovolemia. The risk of air embolism and unsatisfactory hepatic transplant experience have increased the need for rapid transfusion and maintenance of an adequate cardiac volume and pressure while the inferior vena cava was occluded. This is an easier procedure in children whose normal blood volume is lower than in adults. The use of this method enabled the technical problems associated with hepatic and caval injuries to be overcome in three of the five patients, although extensive and additional injuries to other systems allowed only one of them to survive. Other possible management and operative techniques to control the massive hemorrhages are discussed.

1313 A CLINICOPATHOLOGIC STUDY OF HEPATIC DYSFUNCTION FOLLOWING SHOCK. (Eng.) Champion, H. R.; Jones, R. T.; Trump, B. F.; Decker, R.; Wilson, S.; Miginski, M.; Gill, W. (Maryland Inst. Emergency Medicine, Baltimore, MD). *Surg. Gynecol. Obstet.* 142(5):657-663; 1976.

An attempt was made to identify a clinicopathologic syndrome of potentially reversible hepatic dysfunction after severe shock. Among 19 patients admitted to a shock-trauma unit, sixteen patients had profound post-traumatic hemorrhage, 2 had nontraumatic hemorrhage and 1 had profound peripheral vascular collapse secondary to refractory increased intracranial pressure. Four died on the first day post-shock, two died within 4 days, and nine died within 13-55 days. Multiple organ failure and infection developed in the four survivors. The existence of post-traumatic hepatic insufficiency syndrome was suggested and was described in three phases: initiation, function impairment, and recovery of hepatic function. Immediately following shock, there was enzymatic and light and electron microscopic evidence of hepatocellular damage, resulting in a jaundice peak on the 8th-10th day. This was followed by repair and regeneration of the liver as well as an increase in cholestatic enzyme levels. Later, bilirubin peaks were noted when hepatocellular function was further decreased or overloaded against this background of dysfunction related to the episode of shock. Hepatic function recovery might continue or might be delayed by intercurrent disease, particularly systemic infection. It is suggested that support of hepatic function, similar to that used for pulmonary and renal failure cases, may be important in altering the prognosis of trauma patients.

1314 LIVER SCAN AS A MEASURE OF LIVER FUNCTION FOLLOWING JEJUNOILEAL BYPASS FOR MORBID OBESITY. (Eng.) Hollenbeck, J. I.; Brown, R. G.; O'Leary, J. P.; Woodward, E. R. (Coll. Medicine, Univ. Florida, Gainesville, FL). *Surg. Forum* 24:402-404; 1973.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

1334 INFLUENCE OF EXCHANGE TRANSFUSION ON THE DEVELOPMENT OF SERUM IMMUNOGLOBULINS. (Eng.) Mantalenaki-Asfi, K.; Morphis, L.; Nicolopoulos, D.; Matsaniotis, N. ("St. Sophie's Children's Hosp.," Athens, 608, Greece). *J. Pediatr.* 87(3):396-399; 1975.

The influence of exchange transfusion on the development of immunoglobulin (Ig) G, IgA, and IgM blood levels was studied by radial immunodiffusion in 13 neonates. Twenty-five normal and 13 jaundiced (but not exchange-transfused) age-matched infants were used as controls. A high degree of IgG suppression occurred during the first month of life in the exchange-transfused infants and increased during the third ($p<0.001$), sixth ($p<0.01$), and ninth month ($p<0.02$). IgA synthesis was also suppressed in the exchange-transfused infants until the third month p<0.05). IgM, however, was increased immediately fter the transfusion and remained at a higher evel than that of the controls up to the third p<0.05) and sixth (p<0.05) months. Thus, exchange ransfusion seems to delay the production of the nfant's own IgG persistently for 1 yr, as well as ynthesis of IgA for a short time after birth, hereas it accelerates production of IgM.

335 OXYTOCIN AND NEONATAL HYPERBILIRUBINEMIA. (Eng.) Oski, F. A. (Upstate edical Cent., 750 E. Adams St., Syracuse, NY 3210). *Am. J. Dis. Child.* 129(10):1139-1140; 975.

everal hypotheses to explain the previously oberved link between the use of oxytocin during abor and hyperbilirubinemia among newborn infants re discussed. The relative risk of significant aundice ($\geq$ 10 mg/100 ml) in an infant born after xytocin administration is 1.6 times greater than hat of infants born after spontaneous labor or elivery accompanied by amniotomy. This may be xplained by (a) increased RBC mass in the infant, esulting from the redistribution of blood caused y the stimulation of uterine contractions, (b) lteration of the RBC by the drug, (c) stimulation f heme oxygenase activity, (d) inhibition of lucuronyl transferase activity, or (e) interference ith the normal hepatic maturation process of the nfant.

336 A CLINICAL STUDY ON A PEDIGREE OF FAMILIAL NONHEMOLYTIC JAUNDICE (ROTOR TYPE): III. EPORT OF TWO ADDITIONAL CASES. (Jpn.) Ishikawa, .; Doi, M. (Nara Medical Univ., Kashihara, Japan). *. Nara Med. Assoc.* 25(4/5):418-424; 1974.

he father (43-yr-old) and daughter (18-yr-old) of family with a pedigree of familial nonhemolytic jaundice (Rotor type), were clinically examined for jaundice. Neither of them was bothered by any particular jaundice symptoms, but yellowness was present in the skin and in the whites of the eyes. According to their case histories, yellowing became more pronounced when they were tired. No liver bioassay was taken, but the clinical profile of the father agreed with symptoms of Rotor-type constitutional hyperbilirubinemia: slight jaundice of conjunctiva and skin; icteric index, 9; total bilirubin, 1.3 mg/dl (increase of direct bilirubin); BSP retention rate (30-min value, 32.2%; 60-min value, 11.0%); positive cholecystogram; and a very slight delay in incorporation of ^{131}I-BSP into the liver, according to ^{131}I-BSP scintiphotogram. Although yellowing in the daughter increased with tiredness, test results were normal. The authors conclude that the possible clinical nature of the disease cannot be discounted and follow-up examinations should be conducted in subjects with a pedigree of familial nonhemolytic jaundice.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

1341 ASPIRIN HEPATITIS. (Eng.) Zucker, P.; Daum, F.; Cohen, M. I. (Montefiore Hosp., Medical Center, 111 E. 210th St., Bronx, NY 10467). *Am. J. Dis. Child.* 129(12):1433-1434; 1975.

The case reports of two patients with hepatotoxic reactions associated with long-term salicylate therapy are presented. A 17-yr-old girl with systemic lupus erythematosus and an 11-yr-old boy with sickle cell anemia and rheumatoid arthritis manifested chemical hepatic dysfunction and histopathologic changes when serum salicylate concentrations were at or below those levels usually considered safe (30-40 mg/100 ml and 20 mg/100 ml, resp.). The girl had received 3.6 g/day of aspirin and antacids

LIBRARY U. OF I.

for 42 days, while the boy had received 2.4-3.6 g/day of aspirin and antacids for 4 months. Serum SGOT was elevated in both patients, which reverted to normal after salicylate therapy was discontinued. An attempt to reinstitute therapy but maintain a low serum concentration of salicylate in the second patient resulted in a recurrence of hepatic dysfunction. It appears that any child receiving prolonged salicylate therapy should be observed for chemical evidence of hepatotoxicity regardless of serum salicylate concentrations.

1342 ABSENCE OF CELLULAR HYPERSENSITIVITY IN PATIENTS WITH UNEXPLAINED HEPATITIS FOLLOWING HALOTHANE.

(Eng.) Walton, B.; Hamblin, A.; Dumonde, D. C.; Simpson, R. (London Hosp., London, E1 1BB, England). *Anesthesiology* 44(5):391-397; 1976.

Lymphocyte or leukocyte populations from 16 patients with histories of unexplained post-halothane jaundice were exposed to artificially produced conjugates of trifluoroacetate (TFA) with both human liver specific protein (LSP) and human serum albumin (HSA) to determine the association between halothane and postoperative hepatic dysfunction. Blood was taken from eight patients during the acute phase of illness and from the other eight patients at intervals following recovery. Both lymphocyte transformation and leukocyte migration-inhibition tests were undertaken. Lymphocyte transformation responses to the "antigen" TFA-HSA and to the "antigen control" HSA and responses to TFA-LSP and LSP in concentrations between 0.001 and 100 μg/ml demonstrated that there was no significant stimulation in whole-blood cultures from either patients or controls, compared with the positive responses to 50 μg/ml phytohemagglutinin and 10 μg/ml purified protein derivative of human tuberculin (PPD). It is concluded that TFA-HSA and TFA-LSP are not antigenic at those concentrations. Leukocyte migration-inhibition results provided no evidence for cellular hypersensitivity to either TFA-HSA or TFA-LSP. The *in vitro* correlates of cell-mediated immunity in the patients provide no evidence for the hypothesis that the rare occurrence of hepatic dysfunction following exposure to halothane is a manifestation of cellular hypersensitivity.

1343 INVESTIGATIONS ON D-GALACTOSAMINE HEPATITIS AFTER PRETREATMENT WITH ALPHA-HEXACHLOROCYCLOHEXANE.

(Eng.) Schuchhardt, C.; Reutter, W.; Lesch, R. (Pathologisches Institut der Universitat, Albertstrasse 19, D-78, Freiburg, Germany). *Beitr. Pathol.* 157(1):45-55; 1976.

The partially hepatectomized female Wistar rat model of liver proliferation was studied to determine whether galactosamine produces liver injury, whether it influences the proliferative response induced by α-hexachlorocyclohexane (α-HCH), and whether the latter substance acts on the primary or secondary biochemical response of the liver during galactosamine treatment. Animals were sacrificed 12, 20, 24, 36, 48, or 72 hr after a single dose of 200 mg α-HCH/kg. Others received an additional 1 x 375 mg D-galactosamine HCL (GalN)/kg. Still others received a single dose of α-HCH and, 36 hr later, an additional dose of 375 mg D-^{14}C-galactosamine/kg 45 minutes prior to death. The liver was considerably enlarged and liver cell proliferation was induced following α-HCH administration. The enlargement was based upon both a hypertrophy and a hyperplasia of hepatocytes. These proliferating livers showed only slight hepatitis due to galactosamine. Simultaneous application of galactosamine and α-HCH did not protect the liver from injury. The increase in sorbitol dehydrogenase activity was about 30% that in the galactosamine-treated controls if a time interval of at least 8 hr elapsed between the injection of α-HCH and the application of galactosamine. The increase in liver mass due to α-HCH was reduced after additional application of galactosamine, perhaps due to a delayed increase of the proliferative activity by inhibited protein synthesis. During the first 8 hr after α-HCH treatment, galactosamine inhibited the proliferative activity. It is assumed that the metabolic events necessary for the onset of DNA synthesis are also delayed or inhibited in α-HCH stimulated liver tissue after injection of galactosamine. In contrast, 12 hr after α-HCH treatment, stimulation of DNA synthesis was not influenced by galactosamine, indicating that the synthesis of RNA and specific proteins necessary for the onset of DNA synthesis had advanced so far during the prereplicative period that DNA synthesis could no longer be repressed by galactosamine. The morphological signs o hepatitis did not appear or were very mild while uraci nucleotides were trapped and DNA synthesis was inhibited. Thus, α-HCH acts on the level of the secondary biochemical response to galactosamine.

1344 FULMINANT HEPATITIS AND LYMPHOCYTE SENSITIZATION DUE TO PROPYLTHIOURACIL.

(Eng.) Mihas, A. A.; Holley, P.; Koff, R. S.; Hirschowitz, B. I. (Univ. Alabama Medical Center, Birmingham, AL 35294). *Gastroenterology* 70(5):770-774; 1976.

The case of a 24-yr-old woman who developed fulminant hepatitis and lymphocyte sensitization during treatment with propylthiouracil (200 mg 3x/day) and propranolol (10 mg 4x/day) for hyperthyroidism is presented. Clinical and biochemical recovery followed discontinuation of drug therapy. Liver biopsy disclosed submassive hepatic necrosis. During the acute phase of the disease, lymphocyte transformation studies revealed sensitization of the patient's lymphocytes to propylthiouracil but not to propranolol. Sensitization remained demonstrable 2 months after cessation of the former drug. Lymphocytes obtained from a hyperthyroid patient treated with propylthiouracil without complications failed to show evidence of sensitization. These observations indicate that submassive hepatic necrosis may result from treatment with propylthiouracil and are consistent with the theory that sensitization mechanisms may be responsible for the hepatic injury induced by this drug.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

1348 RELATIONSHIP OF HEPATITIS A ANTIGEN TO VIRAL HEPATITIS. (Eng.) Purcell, R. H.; Dienstag, J. L.; Finestone, S. M.; Kapikian, A. Z. (Natl. Inst. Allergy and Infectious Diseases, Building 7, Room 301, Bethesda, MD 20014). *Am. J. Med. Sci.* 270(1):61-71; 1975.

Recent studies on the relation of hepatitis A antigen (HA Ag) to viral hepatitis are reviewed. HA Ag was associated with 27 nm virus-like particles found in the liver and stools of animals experimentally infected with hepatitis A virus (HAV) as well as in the stools of humans experimentally or naturally infected with HAV. Antigen particles with buoyant density of 1.34 were recovered from the liver, but antigen particles with buoyant densities of 1.32-1.40 were recovered from stools. Antigenically, these particles appear to be related; they are probably HAV. Anti-HA Ag antibody was detected in 100% of convalescent sera from patients who were experimentally or naturally infected with HAV, as demonstrated by immune electron microscopy, but it was not detected in the sera of patients with type B hepatitis or non-B hepatitis. The incidence of anti-HA Ag in normal individuals is approximately 50%, and it increases with age. The temporal relation of HA Ag, anti-HA Ag, and liver damage was studied in experimentally infected chimpanzees and humans. It is concluded that type A hepatitis is not serologically related to experimental hepatitis induced by the GB agent of Deinhardt. HA Ag is not serologically related to the fecal antigen of Cross. In addition to immune electron microscopy, complement fixation and immune adherence tests are applied to the detection of HA Ag and anti-HA Ag.

1349 DEVELOPMENT AND CHIMPANZEE TESTING OF A VACCINE AGAINST HUMAN HEPATITIS B. (Eng.) Buynak, E. B.; Roehm, R. R.; Tytell, A. A.; Bertland, A. U.; Lampson, G. P.; Hilleman, M. R. (Merck Inst. Therapeutic Res., West Point, PA 19486). *Proc. Soc. Exp. Biol. Med.* 151(4):694-700; 1976.

The development and evaluation in chimpanzees of a vaccine against hepatitis B or serum hepatitis is described. Highly purified hepatitis B virus surface antigen (Australia antigen) was used to prepare hepatitis B vaccine. Eighty-nine percent of the plasma was from hepatitis B type *ad* donors and 11% from type *ay* donors. The purified antigen was treated with formalin. Conventional safety and sterility tests ruled out possible contamination with exogenous microbial and viral agents in the vaccine, and tests in marmosets ruled out possible contamination with human hepatitis A virus. The vaccine proved very active in inducing antibody against hepatitis B antigen in guinea pigs, monkeys, and chimpanzees. A dose-response curve was obtained for each species. Most vaccinated animals developed antibody against the antigen after three doses of the vaccine containing up to 20 μg of hepatitis B antigen/dose, given 2 weeks or 1 month apart. The vaccine was highly protective in preventing hepatitis in chimpanzees that were challenged by i.v. injection of human hepatitis B virus. All of the six vaccinated chimpanzees were protected against development of antigenemia following challenge with the living virus and none showed complement-fixing antibody against core antigen. The findings may be valuable for the practical control of hepatitis B by highly purified viral antigen vaccine.

1350 DEVELOPMENT AND UTILIZATION OF COMPLEMENT-FIXATION AND IMMUNE ADHERENCE TESTS FOR HUMAN HEPATITIS A VIRUS AND ANTIBODY. (Eng.) Hilleman, M. R.; Provost, P. J.; Miller, W. J.; Villarejos, V. M.; Ittensohn, O. L.; McAleer, W. J. (Merck Inst. Therapeutic Res., West Point, PA 19486). *Am. J. Med. Sci.* 270(1):93-98; 1975.

Complement-fixation (CF) and immune adherence (IA) assays for hepatitis A antigen and antibody were developed as a result of the successful propagation of CR326 strain of human hepatitis A virus in *Saguinus mystax* marmoset livers. Serologic findings in several cases of human infections indicated the development of IA, CF, and neutralizing antibodies in cases of hepatitis A but not in cases of hepatitis B. Hepatitis A antibody appeared after the onset of the disease and persisted for as long as 7 yr. Epidemiological studies using the IA and CF assays were conducted among several Costa Rican families with outbreaks of hepatitis and among several populations in the United States. In Costa

LIBRARY U. OF I. URBANA-CHAMPAIGN

Rica, there was a high incidence of hepatitis A at an early age, while the incidence of hepatitis A antibody among adults in the United States was relatively low. Human immunoglobulins can be standardized for hepatitis A antibody content by the IA assay. Both assays may be useful for detecting hepatitis A virus during virus propagation in cell culture in the laboratory.

1351 RISKS OF HEPATITIS: WHAT CAN BE DONE [LETTER TO THE EDITOR]? (Eng.) Whalen, G. E. (Veterans Admin. Hosp., 500 West National Ave., Wood [Milwaukee], WI 53193). *Gastrointest. Endosc.* 22(1):48-49; 1975.

The potentially high risk of contracting hepatitis among endoscopists and laboratory personnel is discussed. It is suggested that endoscopists and their nurses wear gloves during the procedure and that all patients be treated as potential carriers since screening is impossible. Biopsy forceps should be sterilized between procedures, but this is not feasible for endoscopes. Thorough cleaning of the latter with Betadine® should be sufficient to remove most bacteria.

1352 DISINFECTION OF ENDOSCOPIC INSTRUMENTS [Letter to Editor]. (Eng.) Glouberman, S. (Letterman Army Medical Center, Presidio of San Francisco, CA 94129). *Gastrointest. Endosc.* 22(1): 48; 1975.

To determine whether activated glutaraldehyde is effective in disinfecting endoscopes against viruses, Cidex (activated glutaraldehyde 2%) was added to HBAg positive serum and was incubated for 30 min to 1 week. Radioimmunoassay revealed that the treated sera remained positive for HBAg, indicating that the antigenicity of HBAg was not altered. Heating, acidification or alkalinization, or exposure to pepsin, trypsin, lysozyme, or pancreatic lipase also did not change the antigenicity of HBAg. Previous studies have demonstrated that there may not be a relation between infectivity of the virus and immunologic reactivity. Therefore, it is conceivable that in the Cidex-treated serum, the virus is inactivated.

1353 TISSUE AND ORGAN CULTURE STUDIES OF HEPATITIS B VIRUS. (Eng.) Zuckerman, A. J. (London Sch. Hygiene and Tropical Medicine, Keppel St., London, WCIE 7HT, England). *Am. J. Med. Sci.* 270(1):197-204; 1975.

Studies of tissue and organ culture of hepatitis B antigen (HBAg) are reviewed. By specific attachment of fluorescent antibody to HBsAg and HBcAg, progressive noncytocidal involvement of normal cytoplasmic and nuclear components of cultured liver cells was demonstrated, following inoculation of the cultures of human origin with known infective sera and with clinical material. Particles similar to, if not identical with, the core of the 42 nm hepatitis B Dane particle were demonstrated electron microscopically after several passages in a human diploid cell line derived from liver biopsies from hepatitis from HBAg-negative children after inoculation of cultures with HBV. HBsAg may be produced infrequently in inoculated liver organ cultures, but serial passage has not yet been achieved. However serial passage was achieved in fragments of human embryo liver cultivated on the chorioallantoic membrane of the developing chick embryo. Hepatocytes of cultured explants of liver biopsies from children with chronic HB antigenemia contained intranuclear virus-like particles. Further studies are necessary to determine whether cultivation of hepatitis B virus can be established firmly in readily available cell and organ cultures.

1354 VIRAL HEPATITIS, TYPE B, IN EXPERIMENTAL ANIMALS. (Eng.) Barker, L. F.; Maynard, J. E.; Purcell, R. H.; Hoofnagle, J. H.; Berquist, K. R.; London, W. T. (Bureau of Biologics, 8800 Rockville Pike, Bethesda, MD 20014). *Am. J. Med. Sci.* 270(1):189-195; 1975.

The use of the chimpanzee as a model for hepatitis B virus (HBV) infection is reviewed. This species provides a highly sensitive system for experimental type B hepatitis. With rare exceptions, inoculation of sero-negative chimps with materials containing infectious HBV produces serologic evidence of infection including appearance of circulating hepatitis B surface antigen (HB_sAg) and subsequent development of antibody to HB_sAg and hepatitis B core antigen. Serum enzyme elevations indicative of liver damage have occurred in 31 of 46 animals infected. The antigenic subtypes of HBV in the inocula breed true in the infected animals, and HBV titers of sera containing the adw and ayw subtypes have been established as $10^{7.5}$ infectious units/ml. Rhesus monkeys appear to be less sensitive than chimps, and do not develop evidence of liver damage.

1355 HEPATITIS B ANTIGEN SUBTYPES--HISTORY, SIGNIFICANCE, AND IMMUNOGENICITY. (Eng.) Holland, P. V. (Building 10A, Room 1E-33, Natl. Inst. Health, Bethesda, MD 20014). *Am. J. Med. Sci.* 270(1):161-171; 1975.

Subtypes of hepatitis B surface antigens (HBsAg) are reviewed. Heterogeneity of HBsAg was first demonstrated on agar gel diffusion. Subsequent studies revealed that the group of HBsAg has a group reactive determinant, *a*, plus additional specificities that are not universally present on all antigens. At present, four subtypes are recognized: HBsAg/*adw*, HBsAg/*ayw*, HBsAg/*adr*, and HBsAg/*ayr*. The subtype specificities are viral-determined characteristics and are not host properties. Presently, subtypes are used primarily as epidemiological tools. The subtypes may or may not represent different strains of viral hepatitis type B, may play a role in vaccine development, and may indicate which patients with acute disease will develop fulminant or chronic disease states. Current work on HBsAg subtypes is limited by the ability to find or produce antibodies to other than the *a* or group reactive determinant. The other determinants appear to be less immunogenic than *a*.

1356 ANTIBODY TO HEPATITIS B CORE ANTIGEN.

(Eng.) Hoofnagle, J. H.; Gerety, R. J.; Barker, L. F. (Bureau of Biologics, 8800 Rockville Pike, Bethesda, MD 20014). *Am. J. Med. Sci.* 270(1): 179-187; 1975.

Immunologic responses to viral hepatitis type B (HBV) are reviewed. Two distinct antigen-antibody systems were demonstrated: hepatitis B surface antigen (HBsAg) and antibody (anti-HBs) and hepatitis B core antigen (HBcAg) and antibody (anti-HBc). Three types of serologic response patterns to infection were observed. In the typical patient, HBsAg appears in the serum several weeks after exposure, followed by the appearance of clinical symptoms, and subsequently clearance of HBsAg and development of anti-HBs with clinical recovery. This response of transient HBsAg reactivity is characteristic of 70% of the adult patients. Most patients with transient HBsAg develop anti-HBc. In the chronic carrier state, developing in approximately 5% of the patients, high titers of anti-HBc appear after the development of HBsAg in the serum. In about 25% of patients, serologic response to HBV infection is characterized by the appearance of anti-HBs several weeks after exposure without the presence of HBsAg. Generally, individuals with this type of response do not develop clinical symptoms. Titers of anti-HBc begin to fall with recovery from HBV infection, and anti-HBc appears to be shorter lived than anti-HBs. The authors conclude that anti-HBc testing is important in documenting the occurrence of infection with HBV and is of great value in epidemiologic studies and in evaluating the safety and efficacy of hepatitis B immune globulin and HBV vaccines.

1357 e ANTIGEN IN ACUTE HEPATITIS B. (Eng.)

Norkrans, G.; Magnius, L.; Iwarson, S. (Univ. Goteborg, East Hosp., S-416 85 Goteborg, Sweden). *Br. Med. J.* 1(6012):740-742; 1975.

Ninety patients with acute viral hepatitis type B were studied to examine the association between e antigen and hepatitis B surface antigen (HBs Ag). e Antigen was present in 24 patients; they had detectable levels of HBs AG for significantly longer than did the 66 with no e antigen in their serum. The HBs Ag subtypes D (adw) and (ayw) were similarly distributed among patients with e antigen and among those without. The results of biochemical liver function tests showed no differences between the two groups during the acute phase of illness. Three of the five patients who developed clinical and histological signs of chronic liver disease were positive for e antigen, a finding that supports the hypothesis that the e antigen has a prognostic value in hepatitis B.

1358 GROUND-GLASS HEPATOCYTES IN UNSELECTED LIVER BIOPSIES. ULTRASTRUCTURE AND RELATIONSHIP TO HEPATITIS B SURFACE ANTIGEN. (Eng.)

Winckler, K.; Junge, U.; Creutzfeldt, W. (Medizinische Universitatsklinik, 34 Gottingen, W. Germany). *Scand. J. Gastroenterol.* 11(2):167-170; 1976.

Four hundred unselected liver biopsy specimens were stained with aldehyde-thionin (AT) and examined for ground-glass hepatocytes (GGH). Twenty-eight biopsy specimens containing AT-positive GGH were found in the 61 specimens from hepatitis B surface antigen (HB_sAg)-positive patients, but were never seen in HB_sAg-negative patients. AT-positive GGH were observed in healthy HB_sAg carriers (6/8 biopsies) and in all forms of chronic hepatitis (7/12 with chronic persistent and 8/13 with chronic aggressive hepatitis) but never in acute HB_sAg-positive hepatitis. AT-negative GGH were occasionally seen in HB_sAg-negative patients under drug treatment. Ultrastructurally, GGH showed proliferation of smooth endoplasmic reticulum (SER) that only in AT-positive GGH contained filaments (20-25 nm in diameter) within its cisternae. The results support the hypothesis that there are two different types of liver cells in unselected liver biopsies with similar appearance in conventionally stained sections: AT-positive GGH with filaments in their proliferated SER occurring in HB_sAg-positive patients and AT-negative GGH without filaments occurring in HB_sAg-negative patients under drug treatment.

1359 NUCLEAR BODIES IN THE HEPATIC PARENCHYMAL CELLS IN ACUTE VIRAL HEPATITIS. (Eng.)

Soares, J. O.; de Moura, M. C. (Unidade de Microscopia Electronica, Faculdade de Medicina, Lisboa, Portugal). *Experientia* 31(10):1210-1212; 1975.

Nuclear bodies were detected by electron microscopy in approximately 15% of nucleus actions in the hepatocytes of six patients with acute viral hepatitis. One to four nuclear bodies were found per nucleus, with no differences in frequency or morphology of the bodies in three hepatitis B surface antigen (HBsAg)-positive and three HBsAg-negative patients. The findings of nuclear bodies in hepatitis B as well as in hepatitis A suggest that their presence is probably more related to the viral agent as an "inductor" factor rather than to the type of hepatitis virus. The observations suggest that these structures may express liver cell hyperactivity related to the cellular regeneration after hepatic necrosis, and may also be a reflection of the underlying acute viral process.

1360 MECHANISMS RESPONSIBLE FOR DEFECTIVE HUMAN T-LYMPHOCYTE SHEEP ERYTHROCYTE ROSETTE FUNCTION ASSOCIATED WITH HEPATITIS B VIRUS INFECTIONS.

(Eng.) Chisari, F. V.; Routenberg, J. A.; Edgington, T. S. (Scripps Clinic and Res. Foundation, La Jolla, CA 92037). *J. Clin. Invest.* 57(5):1227-1238; 1976.

The expression of selected lymphocyte surface-membrane markers was evaluated in 37 patients with acute viral hepatitis B. Bone marrow-derived (B) lymphocytes were identified by reference to surface immunoglobulin, whereas normal thymus-derived (T) lymphocytes were assayed by their capacity to form spontaneous nonimmune rosettes with sheep RBC (E rosettes, ER). During the acute and resolving phases of viral hepatitis B, the relative and absolute number of ER-

LIBRARY U. OF I. URBANA-CHAMPAIGN

positive lymphocytes was significantly reduced, whereas the number of surface immunoglobulin-positive lymphocytes and the absolute lymphocyte count remained normal. This resulted in the appearance of a third population of cells, deficient in both surface immunoglobulin and ER markers, and accounting for nearly 25% of peripheral blood lymphocytes. Depression of the number of ER-positive lymphocytes occurred in 55 of 67 individual assays of the 37 cases. Lymphocytes from some patients reacquired ER function when cultured in fetal calf serum but not in the presence of autologous serum, which was capable of suppressing ER function of lymphocytes from normal donors. The extrinsic suppression of ER function by a serum factor (designated as the rosette inhibitory factor), was characterized by a 4 hr latent period and required approximately 18 hr for maximum attenuation of ER function. The serum rosette inhibitory factor was: (a) heat and freeze-thaw stable, (b) nondialyzable, (c) physically separable from hepatitis B surface antigen, (d) not a lymphocytotoxic antibody, and (e) the same buoyant density as a lipoprotein. This extrinsic mechanism was observed in 41.8% of patients with reduced numbers of ER-positive lymphocytes. The rosette inhibitory factor was not detectable in the serum of the remaining 58.2% of the cases of acute and resolving viral hepatitis B despite the presence of reduced numbers of ER-positive lymphocytes. The mechanisms responsible for the suppression of normal ER function in these cases appear to be intrinsic to the lymphocytes and not the result of a humoral factor, because the lymphocytes did not reacquire ER function in the absence of autologous serum. Both intrinsic and extrinsic suppression of T lymphocyte ER function occurred during the first 4 weeks of acute viral hepatitis B. Nine of the 10 patients followed serially continued to manifest defective ER function at 12 weeks. However, the intrinsic defect was observable only in those patients whose liver disease had resolved or was resolving, whereas the extrinsic defect was observed only in two patients with biochemical and histological evidence of unresolved hepatitis.

1361 VIRAL HEPATITIS: CLINICAL ASPECTS. (Eng.) Redeker, A. G. (Univ. Southern California Sch. Medicine, Los Angeles, CA 90007). *Am. J. Med. Sci.* 270(1):9-16; 1975.

The clinical features of viral hepatitis are reveiwed. Acute viral hepatitis usually resolves without sequelae. Fulminant hepatitis, the least common complication of acute hepatitis, is highly lethal, although 20-25% of patients survive. Hepatic failure after 1-3 months of illness is referrred to as subacute (fatal) hepatitis. Ascites due to portal hypertension is common, and at necropsy, submassive hepatic necrosis is usually found rather than the massive necrosis associated with fulminant hepatitis. Two categories of chronic hepatitis are defined: persistent (viral) hepatitis is the benign form, characterized by inflammatory changes in biopsy material, and chronic active hepatitis is a more serious form, which may terminate in hepatic failure. Persistent hepatitis is the most common long-term sequela of acute viral hepatitis. Serum aminotransferases are frequently elevated, but jaundice is not characteristic. Persistent hepatitis may follow both type B and non-B diseases with a frequency of 10-12% and it may appear after complete resolution or late clearance of hepatitis B surface antigen (HBsAg). Chronic active hepatitis embraces both viral and nonviral forms. Jaundice may or may not be present, and episodic jaundice is usually accompanied by large increases in serum transaminases. Chronic active hepatitis sometimes progresses to cirrhosis. Chronic HBsAg is more frequent after initial anicteric hepatitis than after initial icteric hepatitis. In a series of 429 patients with acute icteric type B hepatitis, chronic HBsAg was associated with persistent hepatitis in 6.9% and with chronic active hepatitis in 3%. The persistence of HBsAg for more than 3 months may represent a life-long carrier state.

1362 EPIDEMIC HEPATITIS B: A SUSTAINED OUTBREAK IN A LARGE MILITARY POPULATION. (Eng.) Allen, A. M.; Irwin, G. R.; Karwacki, J. J.; Warren, D. C.; Levine, R. S. (Walter Reed Army Inst. Res., Washington, DC 20012). *Am. J. Epidemiol.* 102(6): 545-552; 1975.

A sustained outbreak of viral hepatitis at an Army base in Texas between January 1971 and June 1973 is described. The epidemiologic investigation was conducted in three phases: initial inquiries, a chart review, and a case control study. There were 792 admissions, but no deaths recorded in a military population of 35,000. Cases were sporadic, with highest attack rates in low ranking soldiers with disciplinary problems. A total of 29% of patients had histories of i.v. drug use within 6 months prior to hospitalization; many of the others had close personal contact with jaundiced persons. Of 505 patients tested by counterelectrophoresis, 31% were seropositive for hepatitis B surface antigen (HBsAg). There were marked differences in rates of exposure to jaundiced persons and shared needles between 38 hepatitis patients and 34 controls. Subtype *ayw* was present in 16/17 antigenemic cases. Seven of nine HBsAg negative cases were antibody positive 3 months later. It is concluded that the epidemic was caused by parenteral drug abuse and personal contact with drug users.

1363 HEPATITIS IN MARMOSETS. (Eng.) Deinhardt, F.; Peterson, D.; Cross, G.; Wolfe, L.; Holmes, A. W. (Rush-Presbyterian-St. Luke's Medical Center, 1753 West Congress Parkway, Chicago, IL 60612). *Am. J. Med. Sci.* 270(1):73-80; 1975.

Studies of the infection of marmosets with human hepatitis A virus (HAV) are reviewed. Some marmoset species [*Saguinus mystax, S. fuscecollis, S. (Oedipomidas) oedipus,* and *Callithrix jacchus,* in order of susceptibility] are susceptible to HAV by either oral or parenteral routes. At least two types of HAV were isolated from marmosets, the two agents having different chemical and antigenic characteristics. Prototypes MS-1 and CR-326 hepatitis strains appear identical, are neutralized by human convalescent sera and pooled immunoglobulin, and result in cross-reacting antibodies. Strain GB appears not to crossreact serologically with MS-1 or CR-326, nor is it neutralized by convalescent sera. GB may be associated with the recently defined type of hepatitis termed hepatitis C or hepatitis non-A/non-B. After repeated challenge, some immune animals develop hyperergic responses with diffuse liver necrosis, and it is suggested that this be considered in future vaccination studies.

1364 EXTRAHEPATIC MANIFESTATIONS OF VIRAL HEPATITIS.

(Eng.) Gocke, D. J. (Rutgers Medical Sch., Piscataway, NJ 08854). *Am. J. Med. Sci.* 270(1):49-52; 1975.

Extrahepatic manifestations of viral hepatitis are reviewed. Three types of syndrome are recognized, a serum sickness-like prodrome of acute hepatitis, polyarteritis nodosa with hepatitis B infection, and glomerulonephritis, also associated with hepatitis B. The serum sickness-like prodrome is characterized by rash, urticaria, polyarthralgia, and sometimes acute arthritis; it occurs in about 15-20% of hepatitis patients (B and non-B). It occurs from 1 to 6 weeks before the onset of icterus and lasts for 2-7 days. Circulating HBsAg-IgM and IgG are often present. Polyarteritis nodosa begins with fever, polyarthralgia, myalgia, rash, and urticaria, and it progresses to peripheral neuropathies, hypertension, eosinophilia, hematuria and azotemia. Fibrinoid necrosis and perivascular inflammation occur in the walls of small arteries. Circulating HBsAg is present. Glomerulonephritis occurs in individuals with chronic active hepatitis and persistent HBs antigenemia. It is usually of the membranous or membranoproliferative type. It is concluded that hepatitis viruses may produce a variety of extrahepatic manifestations in which the mechanism of pathogenesis involves an immunologic process rather than direct viral invasion and cytopathogenicity.

1365 DISORDERED GUSTATORY ACUITY IN LIVER DISEASE.

(Eng.) Smith, F. R.; Henkin, R. I.; Dell, R. B. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032). *Gastroenterology* 70(4):568-571; 1976.

Subjective and objective abnormalities of gustatory function, including decreased taste acuity (hypogeusia), were studied in 22 patients with acute viral hepatitis and 16 patients with chronic liver disease. The chronic liver disease patients included nine with alcoholic cirrhosis, five with postnecrotic cirrhosis, and two with chronic active hepatitis. The patients with acute viral hepatitis, chronic active hepatitis, and with cirrhosis showed subjective and objective disturbances of gustatory function when compared with a normal population. In patients with early hepatitis and with chronic liver disease, the magnitude and uniformity of the threshold elevations were comparable, implying that disordered gustatory function is concomitant with disordered hepatic function. Patients with acute hepatitis showed a significant decrease in taste thresholds (improvement in acuity) as the hepatitis waned, indicating that the gustatory defect is reversible. It is unlikely that copper flux was related to the reversible hypogeusia as changes in serum copper in patients with acute viral hepatitis were insignificant during recovery. Changes in serum zinc and in the concentrations of the components of the plasma retinol transport system were significant; however, no clear correlation was found with measurements of gustatory acuity. Bilirubin, SGOT, and alkaline phosphatase concentrations did not show a relation with measurements of gustatory acuity. The loss of appeal to food may result in a lessening of the impetus to eat. Dysgeusia and hypogeusia along with nausea may be major factors in the anorexia commonly noted in patients with hepatic disease.

1366 FULMINANT SERUM HEPATITIS AND MENINGOCOCCIC MENINGITIS.

(Eng.) Tri, T. B. (Letterman Army Medical Center, Presidio of San Francisco, CA 94129). *JAMA* 234(8):851-852; 1975.

The case report of a 17-yr-old boy who contracted concomitantly fulminant serum hepatitis and meningococcic meningitis is presented. The patient was first observed with fever, arthralgia, and a rash. A counterelectrophoresis test for hepatitis-associated antigen was positive, and increased levels of bilirubin, alkaline phosphatase, lactic dehydrogenase, and SGOT were evident. There was approximately a 10-day delay in the onset of symptoms characteristic of meningitis (i.e., leukocytosis, stupor, and increase in cerebrospinal fluid pleocytosis), supporting the theory that meningitis developed after the onset of hepatitis. The author contends that the patient acquired the nasopharyngeal meningococcal carrier state first; the development of fulminant hepatitis then facilitated the dissemination of meningococci, resulting in the development of meningitis.

1367 HEPATITIS B SURFACE ANTIGEN AND LIVER CELL CARCINOMA.

(Eng.) Williams, A. O. (Dept. Pathology, Univ. Ibadan, Ibadan, Nigeria). *Am. J. Med. Sci.* 270(1):53-56; 1975.

The geographic distribution of the incidence of hepatitis B surface antigen HBsAg is discussed in relation to the incidence of macro- and micronodular cirrhosis and liver cell cancer. High frequencies of HBsAg were observed among healthy populations living in areas (sub-Saharan Africa and the Far East) where there is a high incidence of liver cell cancer and of macronodular cirrhosis, which is frequently complicated by liver cancer. Conversely, low incidences of HBsAg were reported from areas with low incidences of liver cell cancer. Liver cell cancer patients showed a higher incidence of HBsAg than among comparable controls. There is inadequate information on the incidence of HBsAg in liver cell cancer patients. No correlations between the subtypes of HBsAg and liver cancer were observed, nor was there a correlation between HBsAg and α-fetoprotein in liver cell cancer. HBsAg is not common in patients with micronodular cirrhosis with or without complicating liver cancer. It is suggested that HBsAg is necrogenic in the liver and

LIBRARY U. OF I.

is capable of producing hepatic necrosis or hepatitis that may then progress to macronodular cirrhosis or to neoplasia. Possible factors that may influence progression to cirrhosis include malnutrition, immunologic status, age, and viral virulence. Longitudinal studies of carriers may help to elucidate the role of HBsAg in the pathogenesis of liver cell cancer.

1368 CHRONIC LIVER DISEASE DEVELOPING AFTER OUTBREAK OF HBsAg-NEGATIVE HEPATITIS IN HAEMODIALYSIS UNIT. (Eng.) Galbraith, R. M.; Portman, B.; Eddleston, A. L. W. F.; Williams, R.; Gower, P. E. (King's Coll. Hosp., London, SE5 8RX, England). *Lancet* 2(7941):886-890; 1975.

The immunological and histological abnormalities of eight patients with persistently raised serum aminotransferase levels since an outbreak of acute hepatitis in a hospital hemodialysis unit (1968-1970) are reported. After the outbreak, patients were screened regularly and standard biochemical tests of liver function were completed at least every 3 months. Sera were examined for hepatitis B surface antigen (HBsAg) by solid phase radioimmunoassay. Cellular immunity was investigated using the leukocyte migration test with HBsAg as antigen. Liver biopsies of seven patients disclosed chronic aggressive hepatitis in three, with two of the three also having advanced cirrhosis. Chronic persistent hepatitis was present in two others, and the remaining two had nonspecific hepatitis in association with massive iron overload. A higher frequency of cellular immunity to HBsAg was observed in patients who previously had acute hepatitis; however, the prevalance of humoral antibody was similar to that of subjects who had never had acute hepatitis. The high prevalence of anti-HBs in these patients (30% as compared with 7% in healthy controls) may reflect the greater exposure to hepatitis B virus, and is similar to that reported in a healthy laboratory staff handling HBsAg positive material.

LIVER AND BILIARY TRACT

Chronic Hepatitis

1382 CHRONIC ACTIVE HEPATITIS: AETIOLOGICAL CONSIDERATIONS BASED ON CLINICAL AND SEROLOGICAL STUDIES. (Eng.) Dietrichson, O. (Kommunehospitalet, DK-1399 Copenhagen K, Denmark). *Scand. J. Gastroenterol.* 10(6):617-624; 1975.

The incidence and degree of clinical, biochemical, and immunological variables of 85 patients with chronic aggressive hepatitis were analyzed from Danish hospital records collected over a 7-yr period. A frequent association with other diseases was observed; autoimmune disorders occurred in 17 patients. Immunoglobulin (Ig) G was elevated in two/thirds of the patients, while IgA and IgM were generally within the normal limits. Australia (Au) antigen was demonstrated in 19/77 patients. None of the patients had simultaneous occurring Au antigen and circulating autoantibodies (ANF, SMA, and MA). Ten patients had neither Au antigen nor circulating autoantibodies. In the group with autoantibodies, there were more patients with autoimmune disorders among their relatives and with nonhepatic diseases and regular prolonged intake of oxyphenisatin than compared with the Au antigen positive group. The average values for transaminases, bilirubin, IgG, and IgA were significantly higher and serum albumin significantly lower in the patients with ANF and SMA than in those with Au antigen. The increased IgG and IgA values in patients with circulating autoantibodies suggest that immunological factors may be of etiological importance in chronic active hepatitis. Eight of 19 patients with circulating autoantibodies reacted with an increased biochemical activity to an oxyphenisatin challenge, suggesting that this drug may be the primary cause of liver damage in some cases.

1383 THE CONCEPT OF AUTOIMMUNE LIVER DISEASE. (Eng.) Mackay, I. R. (Royal Melbourne Hosp., Victoria, Australia). *Bull. N.Y. Acad. Med.* 52(4):453-465; 1976.

A historical background of the pathogenesis of autoimmune liver disease is presented, and common questions on autoimmunity in disease are discussed. These include: implicating autoimmunity as a direct cause of human disease; defining specific criteria for a disease to be considered autoimmune; detailing how damage is effected in autoimmune disorders; and outlining the manner in which autoimmune states are created, with reference to the forbidden clones theory, cross-reactivity, viral infection, drug allergy, failure of suppressor T cells, genetics, and autoimmune responses. Chronic active hepatitis is recognized as a disease process characterized by a relapsing course, progressive inflammatory destruction of liver cells culminating in cirrhosis, autoimmune serological reactions, and responsiveness to corticosteroid drugs. It is suggested that these are subsets of chronic immunopathic diseases of the liver with degrees of overlap and a common tendency to progress to cirrhosis. The immunopathic stimuli appear to differ among the subsets. It is further suggested that lupoid hepatitis is a candidate autoimmune disease. However, the immunogen responsible for initiating the disease and the antigenic target of the immune attack are still to be identified.

1384 DECREASED INTERFERON RESPONSE BY LYMPHOCYTES FROM CHILDREN WITH CHRONIC HEPATITIS. (Eng.) Tolentino, P.; Dianzani, F.; Zucca, M.; Glacchino, R. (Inst. Infectious Diseases, Univ. Genoa, via 5 Maggio 39, Italy). *J. Infect. Dis.* 132(4):459-461; 1975.

The role of interferon in the pathogenesis of chronic hepatitis was investigated by measuring lymphocyte production of interferon in 16 children with chronic type B hepatitis and in 12 healthy donors. Interferon was induced by the Newcastle disease virus and the parainfluenza virus type 1 (Sendai strain). The yield of interferon was titrated by the Sindbis virus yield-reduction method in monolayers of diploid human embryonic fibroblasts. The amount of interferon produced by the lymphocytes in response to these paramyxoviruses was lower in patients than in healthy donors. In all subjects, interferon titers induced by the viruses were similar. The results suggest that decreased production of interferon may be responsible for the chronicity of this disease.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

1391 STANDARD AND AUGMENTED SECRETIN TESTING IN CHRONIC PANCREATIC ALCOHOLIC DISEASE. (Eng.) Bordalo, O.; Noronha, M.; Lamy, J.; Dreiling, D. A. (Faculty Medicine, Hosp. de Santa Maria, Lisbon, Portugal). *Am. J. Gastroenterol.* 64(2): 125-132; 1975.

Sequential standard (1 U/kg) and augmented (4-5 U/kg) secretin response to the pancreas were compared in normal subjects (30), in alcoholic patients with (26) and without cirrhosis (18), and in subjects with alcoholic pancreatitis (40). The parameters studied were volume, bicarbonate concentration, and rate of secretion of bicarbonate. Normal subjects showed significant elevation of all three parameters after augmented stimulation compared to initial response to standard stimulation. In patients with chronic pancreatitis, a fixation or decrease in the maximum bicarbonate concentration was observed, and in pancreatic carcinoma a fixation or a negligible increase of flow and bicarbonate secretion was seen. The standard stimulus was submaximal for the normal subject only. Among 50 chronic alcoholic patients without cirrhosis undergoing rehabilitation subjected to the same sequential testing, the majority of cases (58%) revealed normal pancreatic function. Among the abnormal responses, 7% showed qualitative insufficiency and 35% had high volumes. In a comparable series of alcoholics with cirrhosis, hypersecretion was seen in 83%. The authors propose that alcohol induces fatty degeneration of the pancreatic cell initially, followed by necrosis and fibrosis.

1392 ALCOHOL AND ABSORPTION FROM THE SMALL INTESTINE. 1. IMPAIRMENT OF ABSORPTION FROM THE SMALL INTESTINE IN ALCOHOLICS. (Eng.) Krasner, N.; Cochran, K. M.; Russell, R. I.; Carmichael, H. A.; Thompson, G. G. (Stobhill General Hosp., Glasgow, Scotland). *Gut* 17(4):245-248; 1976.

Standard screening tests as well as jejunal absorptio tests were performed in 10 chronic alcoholic patients within a few days of admission due to an acute alcoholic episode. Impaired absorption of d-Xylose was noted in three patients and low leukocyte ascorbic acid and serum folate levels were found in five patients. No abnormality was detected in jejunal histology. The absorption of water and electrolytes from the jejunum was studied in these patients, using a triple-lumen tube perfusion system containing 56 mM glucose with phenol red and ^{51}chromatin EDTA as marke (20 ml/min). The mean rate of absorption of water in the alcoholic subjects (50·0 ± 2·3 ml/hr) was significantly lower than the mean value in 14 healthy control subjects (205 ± 15·9 ml/hr). A significant reduction in Na$^+$ and Cl$^-$ absorption was also demonstrated in the alcoholic subjects. These results indicate that patients with acute-on-chronic alcoholism may have a functional impairment of water and electrolyte absorption from the jejunum. This may, in part, account for some of the nutritional deficiencies in such patients and for other symptoms such as diarrhea.

1393 SERUM BILE ACIDS IN ALCOHOLIC LIVER DISEASE. COMPARISON WITH HISTOLOGICAL FEATURE OF THE DISEASE. (Eng.) Milstein, H. J.; Bloomer, J. R.; Klatskin, G. (Grady Memorial Hosp., Emory Univ Sch. Medicine, Atlanta, GA). *Am. J. Dig. Dis.* 21(4): 281-285; 1976.

Fasting serum bile acids were measured by gas-liquid chromatography in 64 patients with alcoholic liver disease and were compared with histological features in their percutaneous liver biopsy specimens. Total bile acid concentrations were normal or minimally increased in six patients in whom fatty infiltration was the only hepatic lesion. In the remaining 58 patients with more severe histological lesions, levels were increased in 93%, whereas serum bilirubins were elevated in only 43%. Chenodeoxycholic acid was usually the predominant serum bile acid, regardless of the degree of necrosis or connective tissue change in the biopsy specimen. Only small amounts of the secondary bile acids, deoxycholic acid, and lithocholic acid, were detected. Levels of these secondary bile acids did not correlate with histological features. This study confirms previous reports that fasting total serum bile acid concentrations are nearly always increased in patients with alcoholic liver disease, with chenodeoxycholic acid usually being the predominant bile acid.

1394 EFFECT OF ALCOHOL ON TOTAL URINARY HYDROXYPROLINE EXCRETION. (Eng.) Wu, A.; Levi, A. J. (Northwick Park Hosp., Watford Rd., Harrow, Middlesex HA1 3UJ, Great Britain). *Am. J. Gastroenterol.* 64(3):217-220; 1975.

The relationship between urinary hydroxyproline and histologic evidence of hepatic fibrosis was investigated, as well as the effect of alcohol on this excretion. Urinary hydroxyproline excretion was measured in 33 patients with abnormal liver function test who were regularly drinking over 80 gm. alcohol daily. Those with changes of cirrhosis on liver biopsy excreted significantly more hydroxyproline than those with normal appearances, fatty change or hepatofibrosis. In 16 patients, the excretion was measured both when they were drinking and when abstaining from alcohol, in the form of several beverages. The rate of excretion was significantly higher 2-7 days immediately following abrupt withdrawal of alcohol. This result raises the possibility that alcoholic beverages may inhibit collagen degradation. If substantiated, it further suggests that the effect of alcohol on collagen metabolism may be of importance in the pathogenesis of alcoholic cirrhosis.

LIVER AND BILIARY TRACT

Cirrhosis

1401 COMBINED PORTAL AND VENA CAVAL HYPERTENSION IN GAUCHER DISEASE: THE VALUE OF PREOPERATIVE VENOGRAPHY. (Eng.) Fellows, K. E.; Grand, R. J.; Colodny, A. H.; Orsini, E. N.; Crocker, A. C. (Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA 02115). *J. Pediatr.* 87(5):739-743; 1975.

A 7-yr-old boy with prior splenectomy in association with Gaucher disease developed portal hypertension, ascites, and obstruction of the inferior vena cava in its hepatic segment, resulting in terminal hepatic failure. Prior to a portacaval anastomosis operation, a localized obstruction of the inferior vena cava at the sub-diaphragmatic level was demon-

LIBRARY U. OF I. URBANA-CHAMPAIGN

strated by caval manometry and inferior vena cavography. The operation lowered portal venous pressure from 47 to 23 cm saline, but in the first few postoperative weeks there was continued hematemesis indicative of inadequate portal decompression, and the patient died. At autopsy, centrilobular hepatic fibrosis appeared to be responsible for the portal hypertension. Nodular enlargement of the right and caudate lobes of the liver was the cause of the caval obstruction, and elevated caval resistance may have contributed to the portal hypertension and failure of the portacaval anastomosis. The value of preoperative inferior vena cavography in addition to arterial portography in children with portal hypertension is stressed.

1402 FIBREOPTIC ENDOSCOPY AND THE USE OF THE SENGSTAKEN TUBE IN ACUTE GASTROINTESTINAL HAEMORRHAGE IN PATIENTS WITH PORTAL HYPERTENSION AND VARICES. (Eng.) Novis, B. H.; Duys, P.; Barbezat, G. O.; Clain, J.; Bank, S.; Terblanche, J. (Groote Schuur Hosp., Observatory 7925, Cape Town, South Africa). *Gut* 17(4):258-163; 1976.

The value of emergency upper gastrointestinal fiberendoscopy, followed by the use of a modified Sengstaken tube when required, was studied during 84 episodes of acute bleeding in 75 patients who had evidence of portal hypertension with varices. The portal hypertension was due to alcoholic cirrhosis in 59 patients and to cryptogenic cirrhosis in 7 of the patients. By definition, varices were present in all patients, but in only 56 episodes were the varices the cause of the bleeding. The correct diagnosis of the source of bleeding was made at endoscopy in 89%. A Boyce modification of the Sengstaken-Blakemore tube was passed in 41 of the 56 episodes of variceal bleeding. It effectively stopped the bleeding primarily in 35 patients but was successful as a final definitive measure in only 19 patients. Only 16 of the patients in whom the tube was passed, survived. The results indicate that the mortality rate may be related to the severity of the bleeding and to hepatocellular dysfunction. Survival increased from 23% in those patients with jaundice, ascites, and encephalopathy on admission to 92% in those without these manifestations. The in-hospital survival rate was 52% in patients bleeding from varices and 64% in those bleeding from other causes, with an overall survival rate of 56%. The results indicate poor prognosis in cirrhotic patients with gastrointestinal bleeding, irrespective of the cause.

1403 A PROSPECTIVE CONTROLLED TRIAL OF AZATHIOPRINE IN PRIMARY BILIARY CIRRHOSIS. (Eng.) Heathcote, J.; Ross, A.; Sherlock, S. (Royal Free Hosp., Pond St., London NW3 2QG, England). *Gastroenterology* 70(5):656-660; 1976.

A prospective controlled trial was conducted with 45 patients (42 women and 3 men) to determine the value of azathioprine (2 mg/kg) in the treatment of primary biliary cirrhosis. Of the 22 patients started on azathioprine, 3 were withdrawn due to severe diarrhea in 2 and temporary bone marrow aplasia in one. The age and duration of symptoms was not markedly different between the treatment and control groups. Pretrial hematological and biochemical tests showed significantly lower hemoglobin values in controls. When pruritus was assessed at periods between 6 months and 5 yr of starting the trial, there was a consistently smaller number of patients with this problem in the treated than in the control group. Laboratory tests showed significant reductions in the WBC count in the treated group at each period of assessment, except at the 4-yr mark. The effect of azathioprine was not reflected in the platelet counts. During the firs year, serum aspartate transaminase levels showed a significant change in favor of the treated group, but this improvement did not continue. Throughout the trial, serum alkaline phosphatase, bilirubin, cholesterol, albumin, and immunoglobulin M values showed no significant change. Titers of serum mitochondrial antibodies became negative more often in treated than in untreated patients. Serial hepatic biopsy specimens demonstrated the development of cirrhosis equally in the two groups. Survival was similar for the first 5 yr of the trial. However, there was a significant difference in favor of the treated group in the 6th yr, although the number of patients available for assessment at that time was so small as to render a definite conclusion impossible.

1404 USE OF BUMETANIDE IN THE TREATMENT OF ASCITES DUE TO LIVER DISEASE. (Eng.) Moult, P. J. A.; Trash, D. B.; Lunzer, M. R.; Sherlock, S. (Royal Free Hosp., Pond St., London NW3 2QG, England). *Postgrad. Med. J.* 51(Suppl 6): 81-84; 1975.

Bumetanide was evaluated in the treatment of 17 patients with chronic liver disease and ascites, with particular emphasis on incidence of complications such as electrolyte disturbances and hepatic encephalopathy. Bumetanide was given at a dose of 1 mg daily. Thirteen of the 17 patients responded; 2 patients responded to a larger dose (2 mg). Three patients were hypokalemic before treatment; 8 of the remaining 14 developed hypokalemia a few days after starting therapy. Hepatic encephalopathy was present initially in six patients; it appeared in two during the course of therapy. Sodium levels were significantly lower during therapy. Two patients died during the initial bumetanide treatment and four others died following the treatment, as a result of their liver diseases. Of 10 patients who were followed up after discharge, 2 required an increased dose to prevent recurrence of ascites and 2 had relapses and died, despite treatment. During treatment, two patients responded to the drug with diuresis, but over the first 9 days, sodium excretion was less than dietary intake. In all, 15 of 17 patients responded satisfactorily to bumetanide, but a potassium sparing diuretic was necessary in 6.

1405 THE CLINICAL SIGNIFICANCE OF CLASSIFICATIONS OF CIRRHOSIS. A COMPARISON BETWEEN CONVENTIONAL CRITERIA AND NUMERICAL TAXONOMY. (Eng.) Winkel, P.; Juhl, E.; Tygstrup, N.; Copenhagen Study Group for Liver Diseases. (Kommunehospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(1): 33-40; 1976.

A group of 441 patients from a randomized clinical trial of prednisone treatment was classified according to different criteria, and the effect of this therapy was assessed by comparing the survival curves of controls and treated patients in the groups. Six classifications based on single criteria were studied: females versus males, alcoholics versus nonalcoholics, compensated versus decompensated cases, active versus inactive cases, manifest versus latent cases, and nonprimary biliary versus primary biliary cirrhosis. The latter group was too small for further analysis. The material was classified by numerical taxonomy, based on 56 clinical symptoms, signs, and histological and serological changes. The taxonomical classification showed interdependence with all the clinical classifications, except that of primary biliary cirrhosis. Three clinical classifications, those based on sex, alcoholism, and compensation, and one taxonomic class showed a significant therapeutic relevance. Combination of these criteria revealed that female patients with compensated nonalcoholic cirrhosis, previously demonstrated to benefit from prednisone treatment, showed a markedly greater prednisone effect if they belonged to the taxonomic group than if they did not. According to clinical, histologic, and laboratory data, the latter group was characterized as less severe cases than the former one. Although the discrepancy between clinical severity and therapeutic effect cannot be fully explained, the data suggest that clinical criteria may not be ideal for selection of cirrhotic patients for steroid therapy, and that numerical taxonomy may provide clues for more clinically significant classifications.

1406 ANDROGEN METABOLISM AND LEYDIG-CELL FUNCTION IN ACUTE AND CHRONIC LIVER DISEASE. (Ger.) Littman, K. P.; Gerdes, H.; Martini, G. A. (Medizinische Klinik der Universitat Marburg/Lahn, Marburg, Germany). *Dtsch. Med. Wochenschr.* 100(38): 1881-1887; 1975.

Diurnal variations of plasma testosterone and urinary excretion rates of testosterone-, androsterone-, aetiocholanolone-, and dehydroepiandrosterone-glucuronide, as well as dehydroepiandrosterone-sulphate were measured in eight patients with alcoholic liver cirrhosis, 10 patients with acute hepatitis, and in four patients with hemochromatosis before and after selective Leydig cell stimulation with 3 x 5000 IU human gonadotrophin. The circadian variation of plasma testosterone and the maximal testosterone concentration after human gonadotrophin stimulation were decreased in patients with cirrhosis and hemochromatosis. In those with acute hepatitis, the diurnal variations were evened out; whereas, individual values were within the normal range. Urinary excretion of free testosterone and testosterone glucuronide was significantly reduced in patients with cirrhosis and hemochromatosis before and after stimulation. The urinary pattern of C_{19} steroid metabolites was markedly changed in favor of the 5-α-steriods in acute hepatitis, cirrhosis, and hemochromatosis.

1407 STUDIES ON CITRATE METABOLISM IN LIVER INJURIES. 1. FASTING BLOOD CITRATE LEVEL IN CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (Eng.) Kaneshige, J. (Okayama Univ. Medical Sch., Okayama, Japan). *Acta Med. Okayama* 29(1):1-8; 1975.

Blood citrate, blood glucose, and serum nonesterified fatty acids (NEFA) in fasting state were measured in 17 patients with chronic hepatitis and liver cirrhosis. Citrate and glucose were measured by enzymatic methods, and NEFA was measured colorimetrically. Fasting blood citrate level rose with the severity of liver diseases, especially in decompensated liver cirrhosis. No significant difference in fasting blood citrate level was found between the subjects with and without glucose intolerance. Fasting blood citrate level had a closer correlation with serum NEFA level than with blood glucose level. It is concluded that the increase in blood citrate level in liver diseases is due to the impaired uptake of citrate by the liver and the increased release of citrate from peripheral tissues.

1408 POTASSIUM STATUS OF PATIENTS WITH CIRRHOSIS. (Eng.) Soler, N. G.; Jain, S.; James, H.; Paton, A. (Dudley Road Hosp., Birmingham, England). *Gut* 17(2):152-157; 1976.

The potassium status of 55 cirrhotic patients was studied in relation to different etiological types of the disease and the influence of factors such as decompensation, carbohydrate intolerance, and diuretic treatment. In addition, the acute and long-term changes in whole-body potassium in relation to the clinical condition and its management were investigated. Of the 55 cases, 34 had alcoholic cirrhosis, 10 had cryptogenic cirrhosis, 8 had chronic active hepatitis, and 3 had hemochromatosis. Whole-body potassium was measured by detecting naturally occurring ^{40}K in a whole body counter. Cirrhotic patients were not always depleted of whole-body potassium, while the majority of alcoholics were depleted. Patients with chronic active hepatitis had normal body potassium stores. Patients with cryptogenic cirrhosis were also depleted but their potassium deficit was not as severe. In general, decompensated patients had low body potassium stores, but only patients with ascites were invariably depleted. One-third of the patients receiving diuretics maintained normal whole body potassium. Diabetes requiring treatment with p.o. hypoglycemic drugs or insulin was not a significant factor in potassium depletion. Eight of 22 fully compensated patients not receiving diuretics were also significantly depleted of potassium, suggesting that in the natural course of cirrhosis, other factors are also important in potassium depletion. The lack of response to potassium supplements, and indications that all patients with an initially normal whole-body potassium maintained this status despite the use of diuretics or corticosteroids over short terms, suggest that treatment is singularly ineffective in changing the potassium status of cirrhotics over the course of a few months. The clinical and prognostic significance of a low whole-

LIBRARY U. OF I.

body potassium in patients with cirrhosis remains a matter for debate.

1409 HYPERTYRAMINEMIA IN CIRRHOTIC PATIENTS.

(Eng.) Faraj, B. A.; Bowen, P. A.; Isaacs, J. W.; Rudman, D. (467 Woodruff Memorial Building, Emory Univ. Sch. Medicine, Atlanta, GA 30322). *N. Engl. J. Med.* 294(25):1360-1364; 1976.

Plasma concentration of tyramine was studied by radioimmunoassay in 8 healthy subjects, 20 hospitalized patients without liver disease, and 13 cirrhotic patients (of whom 7 had hepatic encephalopathy) to evaluate its role in hepatic disorders. The effect of increasing dietary protein on the tyramine level of cirrhotic patients was also assessed. No significant difference in plasma tyramine concentration was seen between normal subjects (1.3 ± 0.1 ng/ml), hospitalized patients without hepatic disease (1.4 ± 0.1 ng/ml) and cirrhotic patients with encephalopathy (2.7 ± 0.5 ng/ml). However, the tyramine level in cirrhotic patients with encephalopathy (6.4 ± 0.1 ng/ml) was significantly higher than in normal subjects or in cirrhotic patients without encephalopathy. Increasing dietary protein from 40 to 80 g/day raised fasting tyramine concentration by 30-70% within 3 days in both encephalopathic and nonencephalopathic cirrhotic patients. Concentration of plasma tyramine in cirrhotic subjects was significantly correlated with that of plasma tyrosine ($p<0.001$).

1410 RELATIONSHIPS BETWEEN TRYPTOPHAN IN SERUM AND CSF, AND 5-HYDROXYINDOLEACETIC ACID IN CSF OF MAN: EFFECT OF CIRRHOSIS OF LIVER AND PROBENECID ADMINISTRATION.

(Eng.) Young, S. N.; Lal, S.; Sourkes, T. L.; Feldmuller, F.; Aronoff, A.; Martin, J. B. (Lab. Neurochemistry, Allan Memorial Inst. Psychiatry, 1025 Pine Ave. West, Montreal, Quebec, Canada H3A 1A1). *J. Neurol. Neurosurg. Psychiatry* 38(4):322-330; 1975.

Tryptophan was measured in the lumbar cerebrospinal fluid (CSF) and serum of patients undergoing neurologic investigation (controls) and in patients with hepatic cirrhosis. Samples were taken from the patients after an overnight fast. Under these conditions, in the controls the mean CSF, free (non-albumin-bound) and total serum tryptophan were in the approximate ratio 1:4:24. In this cross-sectional study, for the controls, CSF tryptophan was correlated significantly and positively with the total serum but not with the free serum tryptophan. In patients with advanced hepatic cirrhosis the mean CSF tryptophan concentration was greatly elevated. However, the mean total serum tryptophan was unchanged and the free serum tryptophan only slightly elevated. Administration of probenecid, which displaces tryptophan from binding sites on serum albumin, increasing the proportion of serum tryptophan in the free form, did not affect CSF tryptophan.

1411 CHOLANGIODYSPLASTIC PSEUDOCIRRHOSIS: LIGHT AND ELECTRON MICROSCOPIC EXAMINATION.

(Eng.) Balazs, M.; Lukacs, V. F.; Denes, L.; Goracz, G. (Janos Hosp. of Budapest Council, 1125, Budapest Diosarok ut 1, Hungary). *Virchows Arch.* [*Pathol. Anat.*] 368(1):61-71; 1975.

The case of a 5-month-old girl with cholangiodysplastic pseudocirrhosis is presented. The infant's brother had died at the age of 5 months with the same condition Electron microscopic examination of a liver biopsy specimen revealed active proliferation of ductular cells and progression of fibrogenesis, findings consistent with the rapid and fatal course of the disease. An acute cholangitis occurred, but after healing, the progression of the original process led to hepatic insufficiency. It is suggested that cholangiodysplastic pseudocirrhosis is a chronic, progressive liver disease; the course of the disease might be hastened by the complication of cholangitis.

1412 NUTRITION IN CRYPTOGENIC CIRRHOSIS AND CHRONIC AGGRESSIVE HEPATITIS. (Eng.)

Morgan, A. G.; Kelleher, J.; Walker, B. E.; Losowsky, M. S. (Airedale General Hosp., Eastburn, Nr. Keighley, England). *Gut* 17(2):113-118; 1976.

A nutritional survey was made of 80 patients with nonalcoholic cirrhosis; 60 had cryptogenic cirrhosis and 20 had chronic aggressive hepatitis. The nutritional status was assessed by determining various nutritional parameters in body fluids. Steatorrhea, present in 44% of the patients, was never severe and was not a major factor in causing nutritional deficiencies. Plasma levels of fat soluble vitamins were low in over a third of the subjects; these low levels were not related to age or steatorrhea. There was no evidence of thiamin deficiency, in contrast with earlier reports on patients with alcoholic liver disease and on chronic alcoholic subjects. A small proportion of the patients had very high urinary N-methylnicotinamide levels as had been reported in earlier studies on alcoholic cirrhosis. Leukocyte ascorbic acid estimations were low in 35% of the patients; this was not age related. It is noted that iron deficiency may mask ascorbic acid deficiency and that leukocyte vitamin C was subnormal in 40% of the patients with a normal serum iron, but only in 10% of those with low serum iron. Low RBC folate occurred in 24% and low serum folate in 17% of the patients, but not always together, and in no case was there megaloblastic change or anemia. Serum B_{12} was low in only three patients and these had a megaloblastic marrow. It is suggested that serum iron and percentage saturation of transferin can be used to indicate iron status in patients with liver disease. The incidence of fat soluble vitamin deficiency (40%) was higher than that of water soluble vitamins, which may reflect malabsorption of fat soluble vitamins due to bile salt deficiency in liver disease. The incidence of nutritional deficiency was less frequent in nonalcoholic as compared with alcoholic liver disease.

1413 HEPATIC LESIONS IN PANCREATITIS. CLINICO-EXPERIMENTAL DATA.

(Eng.) Tuzhilin, S. A.; Podolsky, A. E.; Dreiling, D. A. (Mt. Sinai Sch. Medicine, City Univ. New York, 100th St. and 5th Ave., New York, NY 10029). *Am. J. Gastroenterol.* 64(2):108-114; 1975.

The relation of hepatic and pancreatic lesions was studied in 108 patients with cirrhosis, including 29 autopsy cases of liver cirrhosis, and in 14 dogs with induced pancreatitis. Steatorrhea and creatorrhea of significant magnitude were demonstrated in patients with active cirrhosis by absorption tests with ^{131}I-glyceryl trioleate and ^{131}I-oleic acid. The autopsy findings indicated a parallelism of pathologic changes in the liver and pancreas. In postnecrotic cirrhosis, areas of necrosis were prevalent in the pancreas, while in portal cirrhosis, necrobiosis was absent from the pancreas but sclerosis was prominent. Experimental pancreatitis was induced in 14 adult dogs by injecting 5 ml of duodenal contents into the ligated main pancreatic duct (the minor duct was also ligated). Pancreatitis was produced in 4 dogs by injecting 5 ml of an incubated mixture of blood and trypsin into the ligated ducts. In most of the animals, the liver showed hemorrhage and necrosis, fatty degeneration, disorganization of the lobular structure, congestion, and lymphoid infiltration. Surviving dogs that developed chronic pancreatitis with fibrosis and atrophy had more severe and extensive hepatic lesions. Hepatitis and frank cirrhosis were observed only in the pancreatic fibrosis animals. The hepatic reaction was greater in dogs induced with blood-trypsin mixtures or duodenal contents injected into the main pancreatic duct than in dogs induced with 10% formalin injected into one of the pancreatic arteries. There seemed to be a correlation between the frequency, extent and severity of hepatic lesions and the duration of pathology. The findings do not exclude the possibility that, in man, the etiologic factor producing pancreatitis may be the agent producing hepatic damage.

1414 HEMODYNAMIC EVALUATION OF PATIENTS WITH INTRAHEPATIC PORTAL HYPERTENSION: RELATIONSHIP BETWEEN BLEEDING VARICES AND THE PORTOHEPATIC GRADIENT. (Eng.) Viallet, A.; Marleau, D.; Huet, M.; Martin, F.; Farley, A.; Villeneuve, J.-P.; Lavoie, P. (Hopital Saint-Luc, 1058 St. Denis, Montreal, P.Q., Canada). *Gastroenterology* 69(6):1297-1300; 1975.

A hemodynamic evaluation of 19 patients with intrahepatic portal hypertension and who had bled from varices is presented. Combined hepatic and umbilicoportal catheterization was performed in 17 cases and hepatic vein catheterization in 2. Free portal venous pressure (FPVP), wedged hepatic venous pressure (WHVP), and free hepatic venous pressure (FHVP) were measured. The portohepatic gradient (FPVP-FHVP or WHVP-FHVP) was utilized as an index of portal hypertension. In the 19 patients, the portohepatic gradient ranged from 12 to 24.5 mm Hg (mean of 18.4 mm Hg). The highest values obtained were 24 and 24.5 mm Hg recorded in the two cases of primary biliary cirrhosis. In two patients with postnecrotic cirrhosis, values were 14.5 and 16.5 mm Hg. Two cases of idiopathic portal hypertension had values of 17 and 14.5 mm Hg. In 13 alcoholic cirrhotics, the portohepatic gradient varied between 12 and 21.5 mm Hg (mean of 18.3 mm Hg). These data suggest that in intrahepatic portal hypertension, bleeding varices are observed only if significant portal hypertension exists. Hemodynamic studies may be helpful in evaluating bleeding patients with varices particularly when the origin of the bleeding cannot be determined at endoscopy. The finding of a portohepatic gradient of less than 12 mm Hg strongly suggests that varices are not the source of bleeding.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

1426 DIAGNOSIS AND TREATMENT BY GI ENDOSCOPY. ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY AND SPHINCTEROTOMY OF THE PAPILLA OF VATER. (Eng.) Classen, M. (1 Med. Abteilung, 2000 Hamburg 60, Rubenkamp 148, Hamburg, W. Germany). *J. Norwegian Med. Assoc.* 95(5):293-295; 1975.

The use of endoscopic retrograde cholangio-pancreatography and sphincterotomy of the papilla of Vater in diagnosis is reviewed. Normal criteria for its use include: an emptying time of less than 10 min; a pancreatic duct with maximum dimensions of 4.4 mm for the head, 3.3 mm for the body region, and 2.2 mm for the tail; and a common bile duct with a diameter of 6 mm at the ampulla of Vater, 6.4 mm at the cystic duct, and 4.9 mm below the bifurcation of the hepatic duct. In 100 patients tested, five characteristic changes occurred, usually in combination. These were papillary stenosis, stop of the contrast medium filling within the pancreatic duct, caliber variations and strictures, calcification, and pseudocysts. In 65 of 100, the biliary system was filled retrograde, and pathological changes were seen in all but 10 cases. In all, 77% of the patients presented with pathological changes in the biliary system. There were no changes in the pancreatic duct in 15 of 37 patients and in 27 control subjects given endoscopic retrograde ductography. None of the patients with pathological changes of the pancreatic duct had an intact endocrine system. Pancreatic cancer can be diagnosed by cholangio-pancreatography but this does not solve the problem of early recognition. In 600 patients examined by the technique, side effects included: pain and fever in 6%, a slight increase in amylase in 30%, and a massive amylase increase in 6%. In 85 of 114 patients with jaundice, representation of the efferent bile ducts was successful using endoscopic-radiological means. Endoscopic sphincterotomy of the papilla of Vater was successfully performed with a new device in 10 dogs and in 10 patients with jaundice.

1427 DEVELOPMENT AND EVALUATION OF USE OF CHOLECYSTOKININ IN THE DIAGNOSIS OF ACALCULOUS GALLBLADDER DISEASE. (Eng.) Cohen, W. H.; Freeman, J. B. (Univ. Iowa Coll. Medicine, Iowa City, IA 52242). *Can. J. Surg.* 18(6):571-578; 1975.

Studies on the development and evaluation of use of cholecystokinin (CCK) in the diagnosis of acalculous gallbladder disease are reviewed. Cholecystectomy is of no benefit in approximately 1/3 of those patients with epigastric and right upper quadrant pain. The use of CCK has been proposed to augment cholecystography or biliary drainage procedures, or both, to identify those patients in whom the gallbladder is the source of pain. Radiographic evaluations often are not subjected to adequate, unbiased interpretation, and some follow-up studies are incomplete and of short duration. The authors conclude that despite these objections there is evidence that CCK can be useful as a diagnostic aid, and therefore, continued, controlled, and well-designed studies are warranted.

1428 DIAGNOSIS AND MANAGEMENT OF BILE DUCT STRICTURES. (Eng.) Hermann, R. E. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Am. J. Surg.* 130(5):519-522; 1975.

The success of five different surgical methods used to repair common bile duct stricture was studied in 100 patients for a 2 to 20-yr postoperative period. The surgical methods included: choledochoduodenostomy in 59 patients, resection of the stricture and duct-to-duct repair in 11, choledochojejunostomy in 9, plastic revision of the stricture in 7 and, dilatation and placement of a T tube splint through a difficult recurrent stricture in 14. Excellent (no further symptoms) or good results (mild intermittent symptoms that subsided with medical treatment) were obtained in 84 patients. Sixteen patients had recurring episodes of cholangitis or jaundice or required another operation on the biliary tract. The best results were obtained in patients in whom choledochoduodenostomy was performed.

1429 SPHINCTEROPLASTY AND CHOLEDOCHODUODENOSTOMY FOR BENIGN BILIARY OBSTRUCTIONS. (Eng.)

Rutledge, R. H. (901 South Lake St., Fort Worth, TX 76104). *Ann. Surg.* 183(5):476-487; 1976.

The patient selection techniques, technical details, advantages, and limitations of sphincteroplasty and choledochoduodenostomy for benign biliary obstructions are presented for 73 patients. Sixty patients underwent transduodenal sphincteroplasty; 52 were primary procedures and 8 were secondary. There was no postoperative mortality. Indications for transduodenal sphincteroplasty as the primary operative procedure included stones in the lower end of the duct requiring duodenotomy in 20 patients, failure of passage of #3 or #4 Bakes dilators in 18, primary stones or sludge in 10, and multiple secondary stones in 4. Many patients had a transient hyperamylasemia but only two had pancreatitis. There were no pancreatic or duodenal fistula. None of the patients has any recurrence of jaundice, pain, cholangitis, or any subsequent operation related to the biliary tree. Two of the eight patients for whom this was a secondary procedure continued to suffer from abdominal pain. Choledochoduodenostomy was the primary procedure in the remaining 13 patients. The main indication for this procedure were large primary stones or sludge in seven patients, multiple stones in three, and failure of a #4 dilator in three. There were no significant operative complications, and no related deaths. While both operations are valuable for benign biliary obstructions, sphincteroplasty is preferred as it provides dependent drainage, direct inspection of the ampullary area, and it facilitates the removal of impacted stones and debris. However, choledochoduodenostomy is chosen for elderly poor risk patients or for those patients with pancreatic inflammation or periampullary duodenal diverticula.

1430 CHOLECYSTECTOMY WITH AND WITHOUT SURGICAL DRAINAGE. (Eng.)

Goldberg, I. M.; Goldberg, J. P.; Liechty, R. D.; Buerk, C.; Eiseman, B.; Norton, L. (Univ. Colorado Medical Center, 4200 East Ninth Ave., Denver, CO 80220). *Am. J. Surg.* 130:29-32; 1975.

The need for surgical drainage after simple, uncomplicated cholecystectomy was evaluated by comparing 37 patients who underwent the operation without drainage with 37 patients who had drainage procedures. Both groups demonstrated absence of gross infection and a dry gallbladder bed at the end of surgery, and neither group underwent exploration of the common duct. The operation with drainage had a median duration of 121 min as opposed to 90 min without drainage. There were no deaths in either group. Postoperative fever occurred in 45% of the patients with drainage and in 26.5% of the patients without drainage. Wound infection occurred in 8.1% of the patients with drainage and in none of the patients without drainage. The patients given drainage had a greater total incidence of postoperative complications (19 of 35 as compared to 9 of 34). Postoperative hospitalization duration was longer for patients given drainage (a median of 5 days as opposed to 3 days). The results suggest that surgical drainage after uncomplicated cholecystectomy is unnecessary and may result in increased incidence of morbidity and prolonged hospital stay.

1431 HEPATIC PORTOENTEROSTOMY: AN ASSESSMENT OF ITS VALUE IN THE TREATMENT OF BILIARY ATRESIA. (Eng.)

Campbell, D. P.; Smith, E. I.; Bhatia, M.; Poley, J. R.; Williams, G. R. (Oklahoma Children's Memorial Hosp., P.O. Box 26901, Oklahoma City, OK 73190). *Ann. Surg.* 181(5):591-595; 1975.

The cases of 12 infants who underwent hepatic portoenterostomy for incorrectable-type biliary atresia are reviewed. There was one postoperative death and there were significant postoperative complications in three cases. These included massive upper gastrointestinal bleeding secondary to gastric stress ulcers, intestinal obstruction secondary to adhesions, and upper gastrointestinal bleeding. The mean total survival time was 15.3 months. By 39 months, three infants were still alive. The terminal course in the other nine included upper gastrointestinal bleeding, liver failure, and sepsis. Two of the survivors were in end-stage liver failure. The third had a liver transplant and was doing well at 14 months post-transplant. Assuming the previously reported 10% cure rate, there is a 28% probability that the series was not large enough to show cures with hepatic portoenterostomy.

1432 CHOLANGITIS WITH ACUTE RENAL FAILURE: PRIORITIES IN THERAPEUTICS. (Eng.)

Bismuth, H.; Kuntziger, H.; Corlette, M. B. (Unite de Chirurgie Hepato-Biliaire, Hopital Paul Brousse, 94800 Villejuif, Paris, France). *Ann. Surg.* 181(6):881-887; 1975.

The relation of cholangitis with acute renal failure and therapeutic priorities were studied in 21 patients. The signs of infection were severe and included septicemia and shock (9), obtundation or coma (15), bile duct obstruction caused by lethiasis (13), tumor of the ampulla of Vater (4), and other tumors of the lower duct (4). Only one patient had a history of previous mild renal disease. Twelve had anuria or oligura and nine presented with high output renal failure. Severity and duration of the renal disorder were variable, but there was no statistical correlation between severity and serum bilirubin. Two patients died in shock soon after admission and one refused surgery. Treatment consisted of fluid replacement, furosemide, and antibiotics. Three patients treated with emergency surgery died. Fifteen patients treated with fluid and antibiotic therapy before surgery showed better survival rates. In two patients with persistent sepsis, emergency hemodialysis and surgery resulted in survival in seven cases. Improvement in terms of infection allowed elective surgery in seven cases

LIBRARY U. OF I.

at 8-36 days. Temporary improvement allowed successful emergency surgery when signs returned in two patients. The priority order of therapeutic methods is treatment of infection, treatment of renal failure, and, finally, surgery. Dialysis should be considered in cases requiring emergency surgery.

1433 GALLSTONES AFTER ILEOSTOMY AND ILEAL RESECTION.

(Eng.) Hill, G. L.; Mair, W. S. J.; Goligher, J. C. (The General Infirmary, Leeds, England). *Gut* 16(12):932-936; 1975.

The incidence of gallstones was determined in 108 patients, following ileostomy and ileal resection with particular emphasis on the amount of ileum removed and the nature of the underlying disease (ulcerative colitis in 72 cases, Crohn's disease in 35, and polyposis coli in 1). Evidence of cholelithiasis was obtained by interrogation regarding symptoms or cholecystography using a standard technique with sodium ipodate as the contrast medium. From the necropsy data in three published studies, the expected frequency of gallstones was 2.1% for patients under 40 yr of age and 13.4% for those over 40. However, there was a greatly increased incidence of cholelithiasis with stones demonstrated in 17.1% of those under 40 and 30.5% in those over 40 yr of age. Stones occurred in 15.2% of the men and 31.7% of the women. The frequency of cholelithiasis did not rise with the passage of time since operation. In cases where the amount of ileum resected was more than 10 cm (range, 12 cm to 2 m), there was little difference in the incidence of gallstones between those patients whose original lesion was ulcerative colitis and those who had Crohn's disease. However, in patients who had less than 10 cm of the ileum removed, cholelithiasis was found in only 8 of the 54 patients who had colitis, but in 5 of the 11 who had Crohn's disease. It is suggested that some of the patients with Crohn's disease may have residual or recurrent intestinal disease that caused still further malabsorption of bile acids.

1434 EVIDENCE FOR THE EXISTENCE OF DEFINITIVE HEPATIC CHOLESTEROL PRECURSOR COMPARTMENTS FOR BILE ACIDS AND BILIARY CHOLESTEROL IN MAN.

(Eng.) Schwartz, C. C.; Vlahcevic, Z. R.; Halloran, L. G.; Gregory, D. H.; Meek, J. B.; Swell, L. (Veterans Admin. Hosp. Richmond, VA 23249). *Gastroenterology* 69(6):1379-1382; 1975.

The specific activity-time course curves of a bile fistula patient given both a constant infusion and a pulse of $[^3H]$mevalonic acid were studied to determine precursor-product relations between biliary cholesterol, plasma free cholesterol, and primary bile acids. These curves showed no precursor-product relation between biliary cholesterol, plasma free cholesterol, and bile acids. Both the constant infusion and pulse labeling data indicated that the bile acid precursor had a more rapid rate of turnover than plasma or biliary cholesterol; the biliary cholesterol precursor turned over more rapidly than plasma cholesterol. These data suggest the presence of multiple hepatic cholesterol precursor compartments and that in man, bile acids may be derived predominantly from newly synthesized cholesterol.

1435 A STRUCTURAL STUDY OF GALLSTONES.

(Eng.) Bills, P. M.; Lewis, D. (Univ. Surrey, Guildford, England). *Gut* 16(8):630-637; 1975.

Scanning electron microscopy and micro-x-radiography techniques were applied to a structural study of gallstones from 10 patients. Single and multiple cholesterol stones, calcium carbonate stones, calcium bilirubinate stones, and organic stones without cholesterol were studied. Large differences in structure were observed in stones of similar overall chemical composition. In some cholesterol stones containing calcium carbonate, the calcium carbonate was deposited very unevenly, indicating periods of little or no carbonate deposition during the growth of the stone. Calcium carbonate was often in the form of rare vaterite, and was often present as columns of small disoriented crystals. The cholesterol in such stones was often in large oriented flakes radiating from the center. Fibrous material was present at the center of many of the stones, and it is suggested that this material may have acted as a nucleus for the deposition of other components. No attempt was made to correlate the structure of the stones with the clinical course of the patient.

1436 BILE CANALICULAR ALKALINE PHOSPHATASE AND DISEASE.

(Eng.) Hagerstrand, I. (General Hosp., 214 01 Malmo, Sweden). *Acta Pathol. Microbiol. Scand.* [*A*] 84(3):271-277; 1976.

Seventy nine patients with canalicular alkaline phosphatase activity, without tumor involvement of the liver biopsy specimens were studied. No common causal factors were found for the increase in alkaline phosphatase of the human bile canaliculi. Most of the patients had received drugs and some of these may have influenced the canalicular alkaline phosphatase. Some of the patients were alcohol abusers. The frequency of the Z-gene of alpha-1-antitrypsin was high (9 individuals), 2.5 times higher than that observed in individuals in a random Swedish population. From the laboratory studies, a high sedimentation rate, an electrophoretic pattern of inflammatory reaction without any increase in immunoglobulins, and a moderate increase in serum alkaline phosphatase and gamma-glutamyl transferase activities were found to often coexist with an increased alkaline phosphatase of the bile canaliculi. Thrombocytosis, increased activities of aminotransferases, hepatomegaly, and mild bilirubinemia were less regular findings. Canalicular alkaline phosphatase activity was not related to sex or to blood group. No clinical or laboratory facts were common to all the patients.

1437 SPONTANEOUS BILIARY-ENTERIC FISTULAS: SOME CONSIDERATIONS ON THE MANAGEMENT OF GALLSTONES.

(Eng.) Wolloch, Y.; Glanz, I.; Dintsman, M. (Beilinson Medical Center, Petah Tikva, Israel). *Am. J. Surg.* 131(6):680-683; 1976.

The clinical presentation, diagnosis, treatment, and postoperative complications that occurred in 35 patients (25 women and 10 men, aged 40-81 yr) with biliary-enteric fistulas within the past 10 yr are reviewed. In 17 patients, the fistula was either suspected or diagnosed preoperatively; in 8 patients, the communication of the fistula with the intestine was demonstrated by barium meal, in 4 by barium enema, and in 1 by cholecystography. Three of the 31 patients who underwent surgery died postoperatively, and a fourth died 6 months later. Postoperative complications included burst abdomen (two patients), wound infection (two patients), and leakage from the duodenum with severe peritonitis (one patient). Six patients suffered from previous gallbladder symptoms, and seven others were known to have symptomatic gallstones for a short period varying from 3 months to 1 yr. The evidence indicates that the gallbladder can undergo recurrent episodes of inflammation to the point of fistula development, without any clinical signs and with only minimal symptoms. This supports an active surgical approach to cholelithiasis, even when silent stones are involved.

1438 THE MIRIZZI SYNDROME, INFLAMMATORY STRICTURE OF THE COMMON HEPATIC DUCT. (Eng.) Balthazar, E. J. (New York Medical Coll., Flower and Fifth Ave. Hosp., New York, NY). *Am. J. Gastroenterol.* 64(2):144-148; 1975.

A localized, reversible, inflammatory stricture of the common hepatic duct, secondary to cholelithiasis and cholecystitis (Mirizzi syndrome) is reported in a 47-yr-old man who presented with jaundice. Laparotomy demonstrated a large stone impacted in the neck of the gallbladder, compressing the hepatic artery and hepatic duct. The bile system was cannulated, and significant improvement was demonstrated after 7 weeks. The catheter was withdrawn and the patient was asymptomatic after 7 months. The characteristic roentgenological feature of the Mirizzi syndrome is the presence of broad extrinsic impressions on the lateral aspect of the common hepatic duct and hepatic artery.

GENERAL

1475 REVERSIBLE INTESTINAL MUCOSAL ABNORMALITY IN ACRODERMATITIS ENTEROPATHICA. (Eng.) Kelly, R.; Davidson, G. P.; Rugely, R.; Townley, W.; Campbell, P. E. (20 Collins St., Melbourne, Victoria, Australia 3000). *Arch. Dis. Child.* 51(3):219-222; 1976.

Three cases of acrodermatitis enteropathica that showed similar intestinal mucosal abnormalities on duodenal biopsy are presented. The patients ranged in age between 4-9 months. Initial biopsies taken before treatment showed loss of villous architecture with flattening of villi. There was increased cellularity in the lamina propria due to infiltration with inflammatory cells. The epithelial cells were cuboidal, and the nuclei were enlarged, more rounded, and less elongated with a more open chromatin distribution than normal. After treatment with expressed breast milk and p.o. di-iodohydroxyquinoline (900-1800 mg/day), the rash associated with the disease cleared, and there was partial re-establishment of the villous architecture and reduced cellular infiltration of the lamina propria. When this treatment was replaced by zinc sulfate (50 mg, 2-3 times/day), complete restoration of normal mucosa and complete clinical remission occurred.

1476 ABNORMAL INTESTINAL BILE ACID DISTRIBUTION IN AZOTAEMIC MAN: A POSSIBLE ROLE IN THE PATHOGENESIS OF URAEMIC DIARRHOEA. (Eng.) Gordon, S. J.; Miller, L. J.; Haeffner, L. J.; Kinsey, M. D.; Kowlessar, O. D. (Jefferson Medical Coll., 1025 Walnut St., Philadelphia, PA 19107). *Gut* 17(1):58-67; 1976.

Proximal intestinal bile acids were studied in 14 ambulatory patients with varying degrees of azotemia. The methyl ester-trifluoroacetate derivatives of intestinal and fecal samples were analyzed by gas liquid chromatography on glass columns. Azotemic patients had a significant decrease in deoxycholic acid when compared to nine normal subjects, 12% versus 28%, resp. Analysis of fecal bile acids of a patient with low intestinal deoxycholic acid also showed low deoxycholic acid with a preponderance of primary bile acids, in contrast with fecal bile acids of a normal subject and a patient with normal intestinal deoxycholic acid. It is suggested that impairment of deconjugation or 7α-dehydroxylation might be contributing to the low deoxycholic acid observed in azotemic patients. Unusual bile acids, i.e., ursodeoxycholic acid, 3-hydroxy-7-keto-cholanic acid, and 3,12-dihydroxy-7-keto-cholanic acid were also noted in intestinal aspirates of azotemic patients. The presence of these bile acids in conjunction with low deoxycholic acid correlated with the symptom of diarrhea in azotemic patients, and may contribute to the pathogenesis of diarrhea in these patients.

1477 WATERY DIARRHEA AND HYPOKALEMIA ASSOCIATED WITH INCREASED PLASMA VASOACTIVE INTESTINAL PEPTIDE IN A CHILD. (Eng.) Udall, J. N.; Singer, D. B.; Huang, C. T. L.; Nichols, B. L.; Ferry, G. D. (Baylor Coll. Medicine, Houston, TX). *J. Pediatr.* 88(5):819-821; 1976.

The case of a 7-yr-old boy with watery diarrhea, hypokalemia, normal pancreatic islet cells, and high plasma levels of vasoactive intestinal peptide (VIP) is presented. Small bowel biopsies p.o. showed severely flattened villi, elongation of the crypts, and increased mononuclear cells in the lamina propria. The patient had hypokalemia, flushing spells, and increased vasoactive intestinal peptide (0.7 ng/ml and 3.0 ng/ml in samples drawn on separate days), compatible with the watery diarrhea, hypokalemia, achlorhydria syndrome. Transit time from the ligament of Treitz to the anus was decreased (2 hr and 15 min). A primary disease process may have been responsible for the elevated VIP levels, but no pancreatic or other retroperitoneal tumor, or abnormal islet cells, were found at laparotomy or autopsy. Alternatively, the increased level may have been

LIBRARY U. OF

secondary to diffuse mucosal damage. It is concluded that further investigation of VIP levels in diarrheal conditions is necessary to determine this peptide's significance in pediatric patients.

1478 FINE STRUCTURE OF THE SMALL INTESTINAL MUCOSA IN INFANTILE MARASMIC MALNUTRITION. (Eng.) Brunser, O.; Castillo, C.; Araya, M. (Dept. Nutrition, Univ. Chile, Santiago, Chile). *Gastroenterology* 70(4):495-507; 1976.

The jejunal mucosa was studied in infantile marasmic malnutrition in the early phase after treatment was begun and before the onset of significant weight gain. In seven infants who had weights of at least 40% below normal, light microscopy before recovery showed that the mucosa was normal or midly abnormal in four, and moderately abnormal in three cases. Electron microscopy disclosed abnormalities of the brush border, large autophagosomes and residual bodies, and the deposition of collagen, filaments, and a dense, finely granular material below the basal lamella. Three infants were restudied during recovery. Although the histology remained unchanged, electron microscopy revealed improvement of the brush border, disappearance of the autophagosomes, and smaller and fewer residual bodies. The dense material below the basal lamella was absent whereas the fibrillar components remained. The authors suggest that the fine structural lesions observed may be due to the derangements in cell metabolism caused by the severe, prolonged restriction of protein and caloric intake.

1479 THERAPY WITH GASTRIN ANTIBODY IN THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Hughes, W. S.; Hughes, J. B.; Ritzmann, S. E. (Dept. Medicine, Univ. Texas, Galveston, TX 77550). *Am. J. Dig. Dis.* 21(3):201-204; 1976.

The therapeutic effectiveness of parenterally administered rabbit antigastrin antibody was evaluated in a 27-yr-old woman with the Zollinger-Ellison syndrome and a fasting serum gastrin level of 3,020 pg/ml and a basal gastric acid secretion of 48.9 mEq/hr. Control globulin (5 ml) reduced gastric secretion to 32 mEq/hr. Gastrin antibody (5 ml) reduced it further to 8.7 mEq/hr. Betazole hydrochloride (1.5 mg/kg, s.c.), which was given 75 min after administration of gastrin antibody, stimulated acid secretion to 57.2 mEq/hr. One day later, basal acid secretion was uninhibited, although some antibody activity was present in the patient's serum. The results suggest that gastrin antibody acutely inhibits basal but not betazole-stimulated secretion. The authors conclude that gastrin antibody should not be used for the treatment of Zollinger-Ellison syndrome since the risk of anaphylaxis from this therapy outweighs the short term beneficial effect of acute administration of large amounts of gastrin antibody.

GENERAL

Regional Enteritis

1538 DEVELOPMENT OF A CROHN'S DISEASE ACTIVITY INDEX: NATIONAL COOPERATIVE CROHN'S DISEASE STUDY. (Eng.) Best, W. R.; Becktel, J. M.; Singleton, J. W.; Kern, F., Jr. (Hines Veterans Admin. Cooperative Studies Support Center, Hines IL). *Gastroenterology* 70(3):439-444; 1976.

A study was conducted to develop an index of the over-all activity of Crohn's disease. The study involved 112 patients with Crohn's disease of the small bowel (30%), colon (20%), or both (50%). Forty-six percent of the patients were female; 38% were less than 25 yr of age, while 27% were over 40. Over half of the patients were receiving azulfidine and almost half were receiving prednisone. Information on 18 predictor variables was gathered at each visit. Additionally, the physician rated his over-all evaluation of the patient's status and compared it to the previous visit. A multiple regression computer program was used to derive an equation for prediction of the physician's over-all ratings from a subset of the predictor variables fulfilling a combination of constraints. This equation, numerically simplified and utilizing eight selected variables (stools, pain, well-being, symptoms manifested, Lomotil, abdominal mass, hematocrit, and body weight), is the Crohn's Disease Activity Index (CDAI). Index values of 150 and below are associated with quiescent disease; values above that indicate active disease, and values over 450 are associated with extremely severe disease. The CDAI provides a uniform set of clinical parameters which

LIBRARY U. OF I. URBANA-CHAMPAIGN

can be assessed and recorded in the same way in each of several study centers over a period of years. The numerical index can be used as the principal measure of response to therapy and also can be used to tailor drug dosage to the individual needs of the patient. The CDAI has been used by the National Cooperative Crohn's Disease Study in following over 500 patients, since its inception in 1972.

1539 COURSE AND PROGNOSIS OF CROHN'S DISEASE.

(Eng.) Truelove, S. C.; Pena, A. S. (The Radcliffe Infirmary, Oxford, England). *Gut* 17(3): 192-201; 1976.

Data were collected from a group of 221 patients with Crohn's disease at the Radcliffe Infirmary, during 1938-1970 to obtain definite conclusions about the prognosis of this disease. Of these cases, 166 were new cases and 55 were referred from other institutions after primary diagnosis. These two groups are considered separately as the referred cases are not likely to represent the usual disease pattern. There were slightly more women than men and the predominant age of new cases ranged from the second to the fifth decades. Abdominal pain and diarrhea were common, accompanied by loss of weight, pyrexia, and anemia. Usually both small and large intestine were affected. Many patients showed an extension of their illness during follow-up. Medical measures consisted of treatment for anemia, vitamin supplements, codeine for control of diarrhea, and dietary measures. Corticosteroids and sulfasalazine were used in the 1950s, but immunosuppressive drugs were not used very often until after this series. Only 26% of the new cases and 7% of the referred cases escaped surgery. Many patients had multiple operations. Local complications occurred much more frequently among the referred cases. Acute dilatation of the colon was seen in only one and carcinoma of the colon was seen in four of the new cases. Systemic complications among new cases included arthritis (5), ankylosing spondylitis (3), erythema nodosum (4), and chronic liver disease (3). *Prima facie* evidence was obtained that Crohn's disease showed a fivefold increase over the period covered by this study. Out of 221 patients, Crohn's disease was the probable cause of death in 17 (7.7%). These data demonstrate that patients with Crohn's disease show a poorer rate of survival than the general population and the disease becomes progressively more deadly when it extends over a long period. Age has little effect on prognosis; sex has some influence, as females had a greater number of deaths over 5 yr. No significant differences in survival rate were found among the three main categories (small intestinal, ileocolitic, and primary colonic), but the number of patients in each category was small.

1540 STUDIES ON CROHN'S DISEASE: 1. THE RELATIONSHIP BETWEEN Yersinia enterocolitica INFECTION AND TERMINAL ILEITIS.

(Eng.) Persson, S.; Danielsson, D.; Kjellander, J.; Wallensten, S. (Central County Hosp., Orebro, Sweden). *Acta Chir. Scand.* 142(1):84-90; 1976.

Fifty-two patients with terminal ileitis or regional enterocolitis were examined for signs of infection due to *Yersinia enterocolitica* serotype 3. The patients were grouped according to the length of preoperative history. Among 18 patients with preoperative symptoms of 1 week or less, there were 9 with positive signs of *Yersinia enterocolitica* infection. None of these patients developed the chronic form of Crohn's disease, while two of the primarily *Yersinia*-negative patients progressed to the chronic form. One of nine patients with preoperative symptoms of 1 week to 3 months showed positive signs of *Yersinia enterocolitica* infection. This patient remained healthy, whereas seven of the negative ones progressed to the chronic form of Crohn's disease. None of the patients with established Crohn's disease of the chronic form had signs of recent *Yersinia* infection. The findings indicate that patients with acute terminal ileitis and positive signs of *Yersinia* infection do not usually progress to the chronic form of Crohn's disease. Bacteriologic and serologic investigation for *Yersinia* infection are therefore of prognostic value.

1541 LYMPHOCYTOTOXIC ANTIBODY IN INFLAMMATORY BOWEL DISEASE: A FAMILY STUDY.

(Eng.) Korsmeyer, S. J.; Williams, R. C., Jr.; Wilson, I. D.; Strickland, R. G. (Univ. New Mexico Sch. Medicine, Albuquerque, NM 87131). *N. Engl. J. Med.* 293(22):1117-1120; 1975.

A study of 90 relatives of 23 subjects with inflammatory bowel disease was undertaken to determine the frequency and expression of lymphocytotoxic antibody. Twenty-seven of the 90 relatives demonstrated lymphocytotoxic antibody by a microcytotoxicity method, as compared with only 3 of 69 age, sex, parity, and ethnically matched controls ($p<0.0001$). Decreased lymphocytotoxicity against lymphocytes from patients with inflammatory bowel disease as compared to normal donor lymphocytes previously demonstrated in the serum of probands was also observed in the sera from relatives of the probands. Nineteen of the 48 household contacts of probands were positive for antibody, in comparison with 8 of 42 nonhousehold contacts ($p<0.05$). Eight of 16 spouses of probands showed antibody. The increased prevalence of lymphocytotoxic antibody in family members of probands and its occurrence mainly in household contacts (consanguineous and nonconsanguineous) may indicate the exposure of probands and their relatives to a common environmental agent.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX		
SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

1552 MORPHOLOGY AND FUNCTION OF THE DOG ILEUM AFTER MECHANICAL OCCLUSION. (Eng.) Mirkovitch, V.; Cobo, F.; Robinson, J. W. L.; Menge, H.; Gomba, S. (Hopital Cantonal Universitaire, CH-1011 Lausanne, Switzerland). *Clin. Sci. Mol. Med.* 50(2):123-130; 1976.

To study the mucosal changes in the occluded intestine, complete mechanical occlusion of the ileum was produced in dogs, and the loops above and below the obstruction were examined functionally and morphologically 4 or 7 days later. The intraluminal pressure in the occluded loop never exceeded 8 cm water. The mucosa above the obstruction secreted water and ions into the lumen *in vivo*, although it absorbed glucose normally. Mucosal slices also absorbed amino acids and monosaccharides normally *in vitro*. The mucosa below the obstruction absorbed ions and glucose *in vivo* and nonelectrolytes *in vitro* to a slightly smaller extent than normal intestine. The morphological changes above the occlusion included shorter, plumper villi and shorter crypts, a reduction in histochemically stainable brush-border enzymes, but an increase in acid phosphatase. Below the obstruction, there was atrophy of the villi and crypts and reductions in all enzymes studied. The results suggest that the mucosa above the occlusion possesses an intact and almost normal epithelial layer, but that it has been stimulated to secrete *in vivo*, presumably by intraluminal factors. True atrophy of the mucosa occurred below the obstruction. It is suggested that diminished intraluminal nutrition is responsible for these changes.

1553 A METHOD FOR PREPARING ISOLATED GLANDS FROM THE RABBIT GASTRIC MUCOSA. (Eng.) Berglindh, T.; Obrink, K. J. (Biomedical Center, Univ. Uppsala, Uppsala, Sweden). *Acta Physiol. Scand.* 96(2):150-159; 1976.

A method for isolating gastric glands from the corpus of the rabbit gastric mucosa is presented. The stomach of an anesthetized rabbit was perfused with saline under high pressure through the aorta, taken out, and emptied. The mucosa was stripped off, minced into small pieces, and transferred to a 1 mg/ml collagenase solution. After 90 min at 37 C, a large number of isolated gastric glands and cells were separated. By a simple washing procedure, the glands were freed from cell contamination and collagenase. Using these techniques, gastric glands were viable, as demonstrated by a dye exclusion technique, oxygen consumption, and electrolyte content. For identification of the glandular cells both common staining techniques and electron microscopy were used. Four types of cells were identified: parietal cells, zymogen cells, mucous neck cells, and some endocrine cells. The intracellular morphology of the glandular cells did not differ significantly from that seen in intact gastric mucosa. The glands were stimulated with histamine in a dose-response manner, as revealed by the increase in oxygen consumption (ED_{50}=3 x 10^{-6} M). This isolated gastric gland preparation may serve as a useful tool for new approaches in gastric physiology.

1554 DEMONSTRATION OF THE FUZZY SURFACE COAT OF RAT INTESTINAL MICROVILLI BY FREEZE-ETCHING. (Eng.) Swift, J. G.; Mukherjee, T. M (Inst. Medical, Veterinary Science, Adelaide, South Australia 5000). *J. Cell Biol.* 69(2):491-495; 1976.

The fuzzy surface coat of mucosal cells of the rat rectum was clearly demonstrated by standard freeze-etching procedures. In replicas, the surface coat thickness was seen to be uniform for a particular cell, but it varied among different cells. In contrast to the close-packed layer of branching surface coat filaments observed in most studies of conventionally processed tissues, freeze-etching showed long straight filaments without branching. These were aligned in parallel with one another and with the long axes of the microvilli. The appearance of the surface coat differed substantially from that found in previous thin-section and freeze-etch studies. The significant increase in surface area available for direct contact with substances in the lumen suggests a greater functional role for the surface coat filaments.

1555 THE EFFECT OF PARTIAL STARVATION AND GLUCAGON TREATMENT ON INTESTINAL VILLUS MORPHOLOGY AND CELL MIGRATION. (Eng.) Rudo, N. D.; Rosenberg, I. H.; Wissler, R. W. (Univ. Chicago, Pritzker Sch. Medicine, Chicago, IL). *Proc. Soc. Exp. Biol. Med.* 152(2):277-280; 1976.

The effect of prolonged exposure to augmented glucagon serum concentrations on intestinal mucosal structure and function was investigated in male Sprague-Dawley rats with hormone- or starvation-induced hyperglucagonemia. The rats were either treated with repeated i.p. injections of glucagon (50 µg every 6 hr) or they were partially starved. After 7 days of partial starvation or 5 days of glucagon injections (a time period shown previously to induce increased transport), all animals were sacrificed and a segment of jejunum was removed, fixed in formalin, sectioned, and dipped in Kodak NTB-2 liquid emulsion. After 8 weeks of exposure, the autoradiographs were developed; assessments of villus height and crypt depth and measurements of length of the column of exposed grains were made in a calibrated microscope. The mean villus length in both semistarved and glucagon-treated groups was found to be significantly reduced ($p<0.001$) when compared to control animals. The crypt-to-villus ratio was unaltered by either treatment modality. The rate of cell migration was diminished by both partial starvation and glucagon treatment, but only

LIBRARY U. OF I.

glucagon therapy was found to cause a significant ($p<0.01$) reduction in the rate of cell movement when compared to controls.

1556 HISTOLOGICAL STUDIES ON THE REGENERATION OF SMALL-INTESTINE EPITHELIUM OF RATS IRRADIATED WITH SUBLETHAL DOSES OF X RAYS. (Eng.) Lewicki, Z.; Figurski, R.; Sulikowska, A. (Zaklad Patofizjologii Komorki, ul. Marymoncka 99/101, 01-813 Warsaw, Poland). *Pol. Med. Sci. Hist. Bull.* 15/3(5/6):539-549; 1975.

The dynamics of regeneration of small-intestine epithelium was studied in 62 rats x-irradiated with sublethal doses (550, 600, or 750 R). Twenty-two non-irradiated control animals were used. Specimens of duodenum and jejunum were examined histologically at 1, 2, 4, 6, 8, 14, and 25 days after irradiation. The intestinal villi became shorter and deformed only 1-2 days following irradiation. The blood vessels were damaged, the enterocytes showed features of degeneration and vacuolization, and the epithelium was detached by the exudate accumulating in the stroma. The regeneration of intestinal epithelium was markedly disturbed during days 1-6. On the first and second days after irradiation, the number of epithelial cells of the villi, and particularly of young cryptal ones, markedly dropped. On the fourth and sixth days, increased proliferation of young cryptal cells surpassed the physiological rate. The accompanying disturbances in differentiation consisted of a decreased acidophilic to basophilic cell ratio, and a retardation of maturation of goblet cells. The absolute number of goblet cells in PAS-stained sections was increased, as was their proportion to the number of enterocytes.

1557 BIOCHEMICAL AND MORPHOLOGICAL STUDIES ON HUMAN JEJUNAL MUCOSA MAINTAINED IN CULTURE. (Eng.) L'Hirondel, C.; Doe, W. F.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 50(5): 425-429; 1976.

The combination of a wire-mesh support with the roller-tube technique is described as a procedure for the culture of human jejunal mucosa *in vitro*. The technique was applied to fragments (approximately 10 mg) of jejunal biopsies from 11 normal subjects and from five patients with celiac disease. The cultured tissue was shown by radioautography to incorporate ^{3}H-leucine into proteins of the villus epithelial cells and ^{3}H-thymidine into nucleic acid, predominantly by the enteroblasts. Although the tissue protein and DNA contents fell during culture, the combined tissue and medium DNA content remained constant during culture and could be used as a reference for enzyme and biochemical studies on cultured intestinal biopsies. The authors conclude that jejunal mucosa cultured by the improved roller-tube technique maintains its integrity and displays the usual parameters used to characterize previous culture techniques.

1558 STRUCTURAL CHANGES ASSOCIATED WITH PAROTID "DEGENERATION SECRETION" AFTER POST-GANGLIONIC SYMPATHECTOMY IN RATS. (Eng.) Garrett, J. R.; Thulin, A. (King's Coll. Hosp. Dental Sch., London, England). *Cell Tissue Res.* 162(1):1-12; 1975.

1559 RIBONUCLEOPROTEIN COMPONENTS IN LIVER CELL NUCLEI AS VISUALIZED BY CRYOULTRAMICROTOMY (Eng.) Puvion, E.; Bernhard, W. (Institut de Recherches Scientifiques sur le Cancer, 94800 Villejuif, France). *J. Cell Biol.* 67(1):200-214; 1975.

1560 MYOID FIBRILS IN EPITHELIAL CELLS: STUDIE OF INTESTINE, BILIARY AND PANCREATIC PATHWAYS, TRACHEA, BRONCHI, AND TESTIS. (Eng.) Puchtle H.; Waldrop, F. S.; Meloan, S. N.; Branch, B. W. (Medical Coll. Georgia, Augusta, GA). *Histochemistr* 44(2):105-118; 1975.

1561 SCANNING ELECTRON MICROSCOPIC STUDIES OF MOUSE INTESTINAL MUCOSA AFTER GAMMA AND NEUTRON IRRADIATION [Abstract]. (Eng.) Carr, K. E.; Toner, P. G.; Hamlet, R.; Nias, A. H. W. (Dept. Anatomy and Pathology, Glasgow Univ., Glasgow G31 4PG, Scotland). *Proc. Br. Inst. Radiol.* 48(571): 608; 1975.

1562 SEQUENTIAL MORPHOLOGICAL CHANGES OF ULCERATION IN THE GLANDULAR STOMACH OF RATS INDUCED BY IODOACETAMIDE. (Eng.) Shirai, T.; Takahashi, M.; Fukushima, S.; Tatematsu, M.; Hananouchi, Ito, N. (First Dept. Pathology, Nagoya City Univ., Medical Sch., Nagoya, Japan). *Acta Pathol. Jpn.* 25(4 463-476; 1975.

1563 ELECTRON MICROSCOPIC OBSERVATIONS ON THE INNERVATION OF THE SPHINCTER OF ODDI IN THE DOG. (Eng.) Kyosola, K.; Reehardt, L. (Dept. Anatomy, Univ. Helsinki, Siltavuorenpenger 20b, 00170 Helsinki 17, Finland). *Cell Tissue Res.* 161(2):167-176; 1975.

1564 POSTIRRADIATION REGENERATION OF INTESTINAL EPITHELIUM IN W/W^v AND Sl/Sl^d GENETICALLY ANEMIC MICE. (Eng.) Hopper, A. F.; Russell, E. S. (Dept. Zoology, Rutgers, State Univ., New Brunswick, NJ 08903). *Radiat. Res.* 63(2):310-319; 1975. 1975.

1565 ASPECTS OF INTESTINAL FOLATE TRANSPORT IN THE RAT. (Eng.) Blair, J. A.; Johnson, I. T.; Matty, A. J. (Dept. Chemistry, Univ. Aston in Birmingham, Gosta Green, Birmingham B4 7ET, England). *J. Physiol. (London)* 256(1):197-208; 1976.

In vitro preparations of Wistar rat jejunum were used to study the metabolic dependence, the structural specificity, and the pH sensitivity of the folic acid absorption process. The presence of 2:4 dinitrophenol, and the absence of oxygen in the mucosal bathing medium led to a decrease in the tissue accumulation and serosal transfer of folic acid by everted sacs. 10-Formylfolic acid, present in the mucosal medium at a molar ratio of 10:1 with labeled folic acid, appeared to compete for tissue accumulation sites, but had no significant effect on serosal transfer. The efflux of folic acid from preloaded jejunal sacs was stimulated by the presence in the mucosal medium of folic acid and related compounds. Pteroyl-L-glutamic acid, 10-formylfolic acid, and methotrexate elicited a significant increase in the efflux rate; pteroyl-D-glutamic acid was significantly less effective, and pteroic acid had no effect. The uptake of folic acid by isolated jejunal cells, which were prepared by enzymic disaggregation of the mucosa, was found to be influenced by the pH of the bathing medium, uptake being enhanced at a pH of 5-6. It is concluded that the effect of metabolic inhibitors and acid pH conditions on the uptake of folic acid *in vitro* is consistent with a passive absorption mechanism, influenced in intact preparations and *in vivo* by the jejunal pH microclimate. However, the occurrence of competitive inhibition and stimulated efflux may indicate the existence of a structurally specific accumulation process at some site(s) within the mucosa.

1566 TRANSPORT OF 3-o-METHYL D-GLUCOSE AND β-METHYL D-GLUCOSIDE BY RABBIT ILEUM. (Eng.) Holman, G. D.; Naftalin, R. J. (Dept. Physiology, Univ. London, London WC2R 2LS, U.K.). *Biochim. Biophys. Acta* 433(3):597-614; 1976.

The intestinal transport of β-methyl glucose, 3-*O*-methyl glucose, and D-galactose were studied to determine common features of these actively transported sugars. The apparent affinity constants at the brush border indicated that sugars are selected in the order: β-methyl glucose, D-galactose, and 3-*O*-methyl glucose (the K_m values were 1.23, 5.0, and 18.1 mM, resp.). At low substrate concentrations, the K_t values for Na^+ activation of sugar entry across the brush-border were: 27, 25, and 140 mEq for β-methyl glucose, galactose and 3-*O*-methylglucose, resp. These kinetic parameters suggest that Na^+, water, sugar, and membrane-binding groups are all factors that determine selective affinity. In spite of these differences in operational affinity, all three sugars showed a reciprocal change in brush border entry and exit permeability as Ringer Na or sugar concentration was increased. Estimates of the changes in convective velocity and in the diffusive velocity when the sugar concentration in the Ringer was raised revealed that with all three sugars, the fractional reduction in convective velocity was approximately equal to the (reduction of diffusive velocity)^2. This is consistent with the view that the sugars move via pores in the brush border by convective diffusion. Theophylline reduced the serosal border permeability to β-methyl glucose and to 3-*O*-methyl glucose relatively by the same extent and, consequently, it increased the intracellular accumulation of these sugars. The permeability of the serosal border to β-methyl glucose entry was lower than permeability of the serosal border to β-methyl glucose exit, which suggests that β-methyl glucose may be convected out of the cell across the lateral serosal border.

1567 THE ROLE OF STIMULATED AMINO ACID TRANSPORT IN PROMOTING GLYCOGENESIS IN THE IRRADIATED RAT. (Eng.) Kilberg, M. S.; Neuhaus, O. W. (Univ. South Dakota, Sch. Medicine, Vermillion, SD 57069). *Radiat. Res.* 66(3):597-608; 1976.

Male Sprague-Dawley rats were exposed to two doses of γ rays, (2500 and 1500 r) to demonstrate that hepatic amino acid transport is an important factor in controlling metabolism in the liver, following whole-body exposure to ionizing radiation. Following exposure to 2500 r, the hepatic free amino acids were elevated during the first 48 hr accompanied by a decline in serum levels. At 72 hr, the hepatic amino acids diminished to the control levels, while the serum increased abruptly. In contrast, 72 hr after exposure to 1500 r, the serum amino acid levels increased only 27%, and the hepatic amino acid values increased 52%. These results are explained on the basis of the changes in α-aminoisobutyric acid transport. The incorporation of ^{14}C from labeled L-alanine into hepatic glycogen was maximal 48 hr postexposure to 2500 r, but it declined to below control values at 72 hr. On the other hand, exposure to 1500 r resulted in maximal incorporation of ^{14}C at both 48 and 72 hr. It is proposed that amino acid transport into liver cells is stimulated by the elevated blood levels of amino acids released from the degradation of protein. The transport increased the levels of hepatic free amino acid and is, therefore, a key factor in regulating postirradiation glycogenesis.

1568 EFFECTS OF SALICYLATE AND BILE SALT ON ION TRANSPORT BY ISOLATED GASTRIC MUCOSA OF THE RABBIT. (Eng.) Fromm, D.; Schwartz, J. H.;

LIBRARY U. of I. URBANA-CHAMPAIGN

Quijano, R. (Harvard Medical Sch., Boston, MA 02215). *Am. J. Physiol.* 230(2):319-326; 1976.

The effects of luminal addition of salicylate and taurocholate on ion transport by rabbit fundic mucosa were examined *in vitro* using isotopic and pH stat techniques. Salicylate (3 mM) did not alter ion transport, but 20 mM caused a 40% decrease in the acid secretory rate. Taurocholate (20 mM) caused a transient, apparent cessation of acid secretion followed by stimulation. Salicylate (3 or 20 mM) increased Na$^+$ but not Cl$^-$ permeability at luminal pH 7. At luminal pH 4, however, salicylate increased Cl$^-$ in addition to Na$^+$ and H$^+$ permeability. Taurocholate (10 or 20 mM) increased both cation and anion permeability at pH 7 and pH 4. Addition of salicylate or taurocholate resulted in stimulation of net Na$^+$ transport. While salicylate and taurocholate increased cation permeability at pH 7, they have differing effects on acid secretion and anion permeability. These data suggest that salicylate and taurocholate alter cation permeability by different mechanisms. This is consistent with the concept that enhanced diffusion of H$^+$ into the tissue causes a nonspecific alteration in the permeability pathway.

1569 EFFECT OF BILE SALTS AND FATTY ACIDS ON THE COLONIC ABSORPTION OF OXALATE.

(Eng.) Dobbins, J. W.; Binder, H. J. (Dept. Internal Medicine, Yale Univ. 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 70(6):1096-1100; 1976.

The effect of bile salts and fatty acids on colonic oxalate absorption was investigated in male Sprague-Dawley rats by an *in vivo* perfusion technique. The colon was perfused initially with a 140 mM NaCl control solution and then with the test solution of bile salts and fatty acids. During perfusion with 140 mM NaCl, absorption of 1.5 mM sodium oxalate was 34.2 ± 9.4 nmoles/min/g dry tissue weight, and water absorption was 102.3 ± 31.1 µl/min/g dry tissue weight. In contrast, oxalate absorption increased almost 10-fold to 330.4 nmoles/min/g dry tissue weight ($p<0.001$) during perfusion with 5 mM deoxycholate solution. 5 mM Taurocholate neither increased oxalate absorption nor altered water absorption. Perfusion with 5 mM deoxycholate resulted in a decreased transmural electrical potential difference (PD) from 20.9 ± 1.3 to 9.5 ± 2.6 mv ($n=5$, $p<0.02$). The absorption of 5 mM of urea increased from 254.6 ± 33.9 nmoles/min/g dry tissue weight during the control period to 1738.4 ± 345.9 nmoles/min/g dry tissue weight during perfusion with deoxycholate ($p<0.02$), despite simultaneous water secretion. Perfusion with 20 mM oleic acid increased oxalate absorption and significantly decreased water absorption, although 8 mM oleic acid did not significantly affect either oxalate or water absorption. In contrast, 20 mM octanoic acid, a medium chain fatty acid, did not significantly alter oxalate absorption. Water absorption increased during perfusion with octanoic acid. These results suggest that bile salts and fatty acids increase colonic absorption of oxalate by a nonspecific alteration of mucosal permeability.

1570 THE MECHANISM WHEREBY BILE ACID MICELLES INCREASE THE RATE OF FATTY ACID AND CHOLESTEROL UPTAKE INTO THE INTESTINAL MUCOSAL CELL.

(Eng.) Westergaard, H.; Dietschy, J. M. (Univ. Hosp., DK-2100 Copenhagen ϕ, Denmark). *J. Clin. Invest.* 58(1):97-108; 1976.

The mechanism whereby bile acid facilitates fatty acid and cholesterol uptake into the intestinal mucosal cell was investigated. The rate of uptake (Jd) of several fatty acids and cholesterol was initially found to be a linear function of the concentration of these molecules in the bulk phase, if the concentration of bile acid was kept constant. In contrast, Jd decreased markedly when the concentration of bile acid was increased relative to that of the probe molecule but it remained essentially constant when the concentration of both the bile acid and probe molecule was increased in parallel. In other studies, Jd for lauric acid measured from solutions containing either 0 or 20 mM taurodeoxycholate and saturated with the fatty acid equaled 79.8 ± 5.2 and 12.0 ± 9.4 nmol/min/100 mg, resp.; aft correction for unstirred layer resistance, however, the former value equaled 113.5 ± 7.1 nmol/min/100 mg. Maximum values of Jd for the saturated fatty acids with 12, 16, and 18 carbons equaled 120.8 ± 9.4, 24.1 ± 3.2, and 13.6 ± 1.1 nmol/min/100 mg, resp. Thes values essentially equaled those derived by multiplying the maximum solubility times the passive permeability coefficients appropriate for each of these compounds. The theoretical equations were then derived to define the expected behavior of Jd for the various lipids under these different experimental circumstances. The mechanism of absorption was assumed to occur either by uptake of the whole micelle, during interaction of the micelle with an infinite number of sites on the microvillus membrane or through a monomer phase of lipid molecules in equilibrium with the micelle. The results indicate that the principle role of the micelle in facilitating lipid absorption is to overcome unstirred layer resistance, while the actual process of fatty acid and cholesterol absorption occurs through a monomer phase in equilibrium with the micelle.

1571 INHIBITION OF NaCl ABSORPTION FROM PERFUSED RAT ILEUM BY FUROSEMIDE.

(Eng.) Humphreys, M. H. (San Francisco General Hosp., San Francisco, CA 94110). *Am. J. Physiol.* 230(6):1517-1523; 1976.

The effect of furosemide on intestinal absorption of water and electrolytes was studied using segments of Sprague-Dawley rat ileum perfused *in vivo*. Furosemide (1 mM) in the perfusion fluid reduced absorption of Na, Cl and water by 50% from a balanced electrolyte solution, without changing the transepithelial potential difference (PD). This effect was also observed in the absence of luminal glucose and was largely reversible. Substitution of all Na in perfusion fluid with choline produced secretion of Na and water and abolished Cl absorption; substitution of all Cl with SO$_4$ reduced Na absorption to 20% of control values. Under both of these conditions, furosemide had only trivial effects on electrolyte absorption and it exerted no effect on PD. Measurements of unidirectional fluxes of Na and Cl showed that furosemide decreased net flux by reducing lumen-to-blood flux of these ions rather than increasing blood-to-lumen flux. These results resemble those obtained in this tissue following exposure to acetazolamide, and suggest tnat furosemide inhibits a coupled, neutral process of NaCl transport from lumen to blood. Although this effect could be a result of carbonic anhydrase inhibition, it probably occurs from a separate action of furosemide on ileal transport.

1572 THIAMINE TRANSPORT ACROSS THE RAT INTESTINE. II. EFFECT OF ETHANOL. (Eng.)

Hoyumpa, A. M., Jr.; Breen, K. J.; Schenker, S.; Wilson, F. A. (Veterans Admin. Hosp., Nashville, TN 37203). *J. Lab. Clin. Med.* 86(5):803-816; 1975.

The effect of ethanol on thiamine transport was characterized in Sprague-Dawley rats. Intact isolated duodenal loops were used to measure rates of ^{35}S-thiamine hydrochloride absorption into the circulation *in vivo*, and everted jejunal segments were used to measure net transmural flux, unidirectional uptake, and cellular exit of ^{14}C-thiamine hydrochloride *in vitro*. Intragastric administration of ethanol (50-750 mg/100 g), given 1 hr before the experiment, reduced absorption of low thiamine concentration *in vivo* to 65.44% of the control value. A similar inhibition was noted after i.v. administered ethanol [25, 50, 250, 500, and 750 mg/100 g as 2.5, 5, 25, 50, and 39% (weight/volume) solutions, resp.]. Once attained, the inhibition of thiamine absorption was not related to the ethanol dose or to ethanol concentration in the blood or in the intestinal lumen; this inhibition was reversible. In contrast, ethanol did not affect absorption of high concentrations of thiamine. These findings were confirmed by the *in vitro* results. In transmural flux studies, the movement of low, but not of high, thiamine concentration against a concentration gradient was inhibited by ethanol, so that the normal serosal/mucosal ratio of 1.5 was reduced to 1.0. Ethanol did not affect unidirectional uptake into the mucosa of either low or high thiamine concentrations, but it did block cellular exit of low thiamine concentrations from the cells into the serosal compartment. Exit of high thiamine concentrations was not affected. Ouabain (100 μM), like ethanol, markedly reduced cellular exit but did not influence uptake of low thiamine concentrations. These studies suggest that ethanol adversely affects the active, but not the passive, component of thiamine transport. Moreover, ethanol appears to block thiamine exit from the cells but does not affect cellular uptake of thiamine. The similarity to ouabain action suggests that ethanol may impair active thiamine transport by inhibiting Na-K adenosine triphosphatase activity.

1573 SODIUM/PROTON ANTIPORT IN BRUSH-BORDER-MEMBRANE VESICLES ISOLATED FROM RAT SMALL INTESTINE AND KIDNEY. (Eng.)

Murer, H.; Hopfer, U.; Kinne, R. (Max-Planck-Institut fur Biophysik, Frankfurt/Main, W. Germany). *Biochem. J.* 154(3):597-604; 1976.

Studies on proton and Na$^+$ transport by isolated intestinal and renal brush border-membrane vesicles were performed in male Wistar rats to test for the presence of an Na$^+$/H$^+$-exchange system. Proton transport was evaluated as proton transfer from the intravesicular space to the incubation medium by monitoring pH changes in the membrane suspension induced by sudden addition of cations. Na$^+$ transport was determined as Na$^+$ uptake into the vesicles by a filtration technique. A sudden addition of sodium salts (but not choline) to the membrane suspension provoked an acidification of the incubation medium, which was abolished by the addition of 0.5% Triton X-100. Pretreatment of the membranes with Triton X-100 prevented the acidification. The acidification was not observed if the [K$^+$] and proton conductance of the membranes were increased by the simultaneous addition of valinomycin (1 μl) and carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone (1 μl) to the K$^+$-rich incubation medium. Either valinomycin or carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone, when added alone, did not alter the response of the membranes to the addition of Na$^+$. Na$^+$ uptake by brush border microvilli was enhanced in the presence of a proton gradient directed from the intravesicular space to the incubation medium. Under these conditions, a transient accumulation of Na$^+$ inside the vesicles was observed. It is concluded that intestinal and renal brush border membranes contain a Na$^+$/H$^+$ antiport system that catalyzes an electroneutral exchange of Na$^+$ against protons and consequently can produce a proton gradient in the presence of a concentration difference for Na$^+$. This system may be involved in the active proton secretion of the small intestine and the proximal tubule of the kidney.

1574 UPTAKE OF CIRCULATING IRON BY THE DUODENUM OF NORMAL MICE AND MICE WITH ALTERED IRON STORES, INCLUDING SEX-LINKED ANEMIA. HIGH RESOLUTION RADIOAUTOGRAPHIC STUDY. (Eng.)

Bedard, Y. C.; Pinkerton, P. H.; Simon, G. T. (Dept. Pathology, Univ. Toronto, Toronto, Ontario, Canada M5G 1L5). *Lab. Invest.* 34(6):611-615; 1976.

The deposition of i.v.-administered iron in the duodenal epithelium was studied by electron microscopy radioautography in normal mice, in iron-overloaded and iron-deficient mice, and in mice with X-linked anemia (gene symbol sla), 4 and 24 hr after injection of ^{59}Fe. The resolution of radioautography with ^{59}Fe was determined with a line source and the distance from the hot line within which half of the grains fell (HD value) was 1650 A. In normal, iron-overloaded, and sla mice, radioiron was localized in the undifferentiated crypt cells at 4 hr and in the absorptive cells of the luminal half of the villi, at 24 hr. At both times, the vast majority of the grains was seen over the areas rich in free ribosomes and rough endoplasmic reticulum. In iron-deficient mice, grains were not found at either

LIBRARY U. S.

time. The amount of iron incorporated in the crypt cells was related to the size of the body iron stores. It is postulated that the amount of iron incorporated in the crypt cells is the result of interaction between uptake and return to the blood of the circulating iron. Once the crypt cells have differentiated into absorptive cells, the uptake and recirculation of iron from and to the blood ceases, leaving an amount of "message" iron that determines the absorptive cell's subsequent capacity for iron transfer to the plasma. In sla mice, in spite of tissue iron deficiency, the amount of iron deposited was similar to that of normal mice and it was markedly increased after treatment of the anemia. The accumulation of iron in the crypt cells may result from the decreased return to the blood of the incorporated circulating iron, due to the postulated deficient iron carrier mechanism in sla, or it may be a consequence of increased avidity of the absorptive cells for circulating iron. In either event, the absorptive cell receives an inappropriate message with resulting inappropriate iron absorption.

1575 COLONIC ABSORPTION OF BACTERIALLY SYNTHESIZED VITAMIN K_2 IN THE RAT. (Eng.) Hollander, D.; Muralidhara, K. S.; Rim, E. (Harper Hosp., Detroit, MI 48201). *Am. J. Physiol.* 230(2):251-255; 1976.

Colonic absorption of bacterially synthesized vitamin K_2 ([^{3}H]menaquinone-9) was studied *in vitro* with everted rat colonic sacs. The mean rate of absorption of the vitamin by the colon was approximately 20 pmol/min/100 mg tissue at 300 nM mucosal concentration of the vitamin. The rate of absorption did not change with the addition of 2,4-dinitrophenol, Na azide, or KCN to the mucosal incubation medium. No evidence for transmural transport of the vitamin was detectable. When the concentration of vitamin K_2 was increased in a stepwise fashion up to 900 nM, the absorption rate remained linear with respect to the mucosal fluid concentration (r=0.98). Autoradiography indicated that the vitamin accumulated in the mucosal and submucosal layers of the large bowel. Absorption of the vitamin by the large bowel takes place via a passive, nonsaturable process that shows no evidence of energy dependence or carrier mediation. It is concluded that vitamin K_2 (bacterial origin) is absorbable by the rat colon in amounts sufficient to meet the daily requirement of the animal, and this may explain the lack of bleeding problems in the face of episodic lack of dietary vitamin K.

1576 FACILITATED TRANSPORT OF UREA ACROSS THE TOAD GALLBLADDER. (Eng.) Curci, S.; Casavola, V.; Cremaschi, D.; Lippe, C. (Inst. General Physiology, Univ. Bari, Via Amendola 165/A, I-70126 Bari, Italy). *Pfleugers Arch.* 362(2):109-112; 1976.

MOTILITY

1592 GASTRODUODENAL MOTOR GRADIENTS IN THE DOG AFTER PYLOROPLASTY. (Eng.) Ormsbee, H. S., III; Bass, P. (Univ. Maryland Sch. Medicine, Baltimore, MD 21201). *Am. J. Physiol.* 230(2):389-397; 1976.

Circular muscle contractile activity of the antrum and duodenum and gastric emptying of a liquid test meal were investigated in four unanesthetized dogs in which the gastroduodenal junction (GDJ) was altered by Heineke-Mikulicz pyloroplasty. The motor activity in these dogs was compared with that in four controls. Five extraluminal strain gage force transducers were sewn to the serosal surface in the transverse axis of the stomach and duodenum in all dogs to record circular muscle activity. After pyloroplasty, antralization (antral-like contractions occurring in the first portion of the duodenum) was observed during the digestive state. Antralization replaced the normal periods of inhibition that separated periods of duodenal contractions during the interdigestive burst. Bethanechol (0.1 mg/kg, s.c.) and metoclopramide (2.0 mg/kg, i.v.) were capable of stimulating interdigestive contractile activity in the altered GDJ. Pentagastrin (1.0 μg/min, i.v.) produced a differential stimulation on the antrum without appreciably affecting duodenal contractile activity. Pyloroplasty also enhanced the emptying of a 300-ml citrate-fat liquid test meal. An intact hypomuscular segment between the antrum and duodenum is important for normal coordinated contractile activity between the antrum and the duodenum and for the normal gastric emptying of liquids.

1593 EFFECT OF A GASTRIN-LIKE PEPTIDE ON ELECTRICAL AND CONTRACTILE ACTIVITIES OF CANINE STOMACH. (Eng.) Akaike, N. (Kumamoto Univ. Medical Sch., Kumamoto, Japan). *Kumamoto Med. J.* 28(2):94-99; 1975.

The effect of a gastrin-like amyloxycarbonyl tetrapeptide (AOC) was investigated in the stomachs of 36 dogs by recording electrical and mechanical activities of the antrum. The "pacesetter potential," recorded with a suction electrode, consisted of a triphasic spike potential, followed by a monophasic slow potential. The slow potential amplitude was increased by AOC (0.6 μg/kg, i.v.), gastrin (0.6 μg/kg), histamine (30 μg/kg), and cholinergic drugs, while the spike potential was not affected by any drugs. However, frequency of the pacesetter potential was increased by both AOC and gastrin, but decreased by histamine and cholinergic drugs. All drugs increased antral contractions. Comparing the effects of atropine (1 mg/kg) and hexamethonium (2 mg/kg) on the electrical and mechanical responses to AOC with those to histamine and cholinergic drugs, it is concluded that AOC is more similar to cholinergic drugs than to histamine in its effect on the antrum.

LIBRARY U. OF

1594 EFFECTS OF 13-nle-MOTILIN ON THE ELECTRICAL AND MECHANICAL ACTIVITY OF THE ISOLATED PERFUSED CANINE STOMACH AND DUODENUM. (Eng.) Green, W. E. R.; Ruppin, H.; Wingate, D. L.; Domschke, W.; Wunsch, E.; Demling, L.; Ritchie, H. D. (London Hosp. Medical Coll., London, England). *Gut* 17(5): 362-370; 1976.

The direct actions of synthetic 13-norleucine-motilin (13-nle-motilin) on myoelectrical activity and intraluminal pressure were studied in the isolated vascular-perfused canine stomach and duodenum. Intraluminal pressure was recorded by a triple lumen water-filled nonperfused open-tip tube, connected to a recorder. Myoelectrical activity was monitored by silver-chloride electrodes sutured to five sites on the serosal surface of stomach and duodenum. Increasing doses of 13-nle-motilin (40, 80, 160, 320, and 640 ng) were administered. 13-nle-motilin increased intraluminal pressure in the pylorus and duodenum, and dose-response analysis showed the duodenum to be twice as sensitive as the pylorus to the polypeptide. Pressure changes in the antrum were small and not dose-related, but, whereas the basic electrical rhythm in the duodenum was not altered, slow wave frequency, rhythm, and propagation in the antrum were disturbed. Electronic analysis of the duodenal spike increase, which accompanied pressure rises, demonstrated correlations between increases in spikes, intraluminal pressure, and dose. These results show that the direct effect of the polypeptide on adjacent organs may explain the combination of increased motor activity, with delayed gastric emptying as a consequence of disturbance in the coordination between antrum, pylorus, and duodenum.

1595 MECHANISM OF ACTION OF PENTAGASTRIN ON THE LOWER ESOPHAGEAL SPHINCTER. (Eng.) Zwick, R.; Bowes, K. L.; Daniel, E. E.; Sarna, S. K. (Surgical Medical Res. Inst., Univ. Alberta, Edmonton, Alberta, Canada). *J. Clin. Invest.* 57(6): 1644-1651; 1976.

The effect of pentagastrin on lower esophageal sphincter (LES) pressure was studied in three unanesthetized dogs. LES pressure was monitored by an infusion manometric technique. Increasing doses of pentagastrin up to 3 µg/kg, given as an i.v. bolus, resulted in increasing rises in LES pressure; larger doses resulted in a lesser effect of shorter duration. Increasing i.v. boluses of methacholine produced greater increases in LES pressure up to a maximum of 5 µg/kg; higher doses had similar effects. Atropine (50-100 µg/kg) slightly diminished the response of the LES to 2 or 6 µg/kg of pentagastrin. In large doses (500-2,000 µg/kg), atropine did not diminish the response to pentagastrin and prolonged the response of 6 µg/kg pentagastrin. Hexamethonium (2 mg/kg, i.v.) slightly depressed the peak response to 3 µg/kg pentagastrin, but the response to 6 µg/kg was increased and prolonged. Propranolol (2 mg/kg, i.v.) significantly prolonged the effect of 6 µg/kg pentagastrin on the LES. It is concluded that the stimulatory effect of pentagastrin is mainly due to a direct action on the LES. A lesser stimulato effect is due to an action on preganglionic cholinergic neurons.

1596 GENESIS OF BASAL SPHINCTER PRESSURE: EFFECT OF TETRODOTOXIN ON LOWER ESOPHAGEA SPHINCTER PRESSURE IN OPOSSUM IN VIVO. (Eng.) Goyal, R. K.; Rattan, S. (Southwestern Medical Sch., 5323 Harry Hines Blvd., Dallas, TX 75235). *Gastroenterology* 71(1):62-67; 1976.

The role of neural and myogenic activity in the genesis of resting sphincter pressure was evaluated in the opossum. The neural activity in the sphinct was blocked by i.v. administration of the puffer fish poison, tetrodotoxin, in intact animals. Ther was considerable variation among animals regarding the dose of tetrodotoxin required to produce adequate blockage of all of the neurally stimulated responses (10-60 µg/kg). A respirator was used to assist breathing; blood pressure was supported by i.v. administration of Ringer's solution; and body temperature was maintained by a heating lamp. The lower esophageal sphincter pressures were measured with water-filled and continuously perfused catheters, which were anchored to the lower esophageal sphincter using anchoring pins. Tetrodotoxin (10 µg/kg) blocked the sphincter response to neural stimulation with vagal stimulation, esophageal distention, and local electrical stimulation of the sphincter. The mean resting sphincter pressure before tetrodotoxin was 59.0 ± 2.6 mm Hg, and it was 64.4 ± 6.9 mm Hg after tetrodotoxin ($p>0.05$). During neural block with tetrodotoxin, the sphincte response to administration of isoproterenol (2.5 µg/kg) or bethanechol (20 µg/kg) was similar to tha during the control period ($p>0.05$). Results indica that: tetrodotoxin can be administered in intact animals to achieve complete blockage of neural acti ity in the lower esophageal sphincter; sphincter muscle is not adversely affected by tetrodotoxin; and blocking neural activity does not alter the res ing lower esophageal sphincter pressure.

1597 STUDIES ON THE MECHANISM OF ESOPHAGITIS-INDUCED LOWER ESOPHAGEAL SPHINCTER HYPOTENSION IN CATS. (Eng.) Higgs, R. H.; Castell, D. O.; Eastwood, G. L. (U.S. Naval Hosp., 17th and Pattison Ave., Philadelphia, PA 19145). *Gastroenterology* 71(1):51-57; 1976.

The effects of experimental esophagitis on the lower esophageal sphincter (LES) response to edrophonium, pentagastrin, and bethanechol were studied This was based upon the findings that perfusion of 0.1 N HCL 5 cm above the LES in cats, for 30 min on 4 consecutive days produced biopsy-documented esophagitis and marked decreases in LES pressure. The sphincter response to both edrophonium (100 µg/kg, i.v.) and pentagastrin (0.6 µg/kg, i.v.), after esophagitis was induced, was significantly less tha preperfusion responses. When the esophagitis was resolved, the pressure response to edrophonium and pentagastrin returned to preperfusion levels. In contrast, the sphincter response to bethanechol (25 μg/kg, i.v.), during esophagitis, was not different from the preperfusion response and it remained unchanged after resolution of the esophagitis. Lower esophageal smooth muscle taken from cats with active esophagitis appeared normal by both light and electron microscopy. These studies indicate that besides decreasing resting LES tone, esophageal inflammation causes functional impairment of a cholinergic mechanism regulating LES pressure. In contrast, the smooth muscle appears to be unaffected by inflammation, despite the LES hypotension.

SECRETION AND METABOLISM

Stomach

1617 SEX-RELATED DIFFERENCE IN ANTRAL AND SERUM GASTRIN LEVELS IN THE RAT. (Eng.) Lichtenberger, L. M.; Nance, D. M.; Gorski, R. A. (Veterans Admin. Wadsworth Hosp. Center, Building 115, Room 115, Los Angeles, CA 90073). *Proc. Soc. Exp. Biol. Med.* 151(4):785-788; 1976.

Antral and serum gastrin levels were measured by radioimmunoassay in normal male and female Sprague-Dawley rats, in ovariectomized rats with and without estrogen treatment, and in mother rats during their third week of lactation. Males had a significantly higher serum gastrin concentration than did female rats; however, this level was significantly increased to male levels following ovariectomy. Daily treatment with 2 μg of estradiol benzoate for 14 days decreased the serum gastrin concentration in ovariectomized rats to the levels in normal females. Following ovariectomy, antral gastrin levels also increased, but not significantly. Both antral and serum concentrations were significantly higher in lactating rats than in any other group ($p<0.01$). The results indicate that there are reliable sex differences in antral and serum gastrin concentrations and that the low serum gastrin levels in intact normal females may be due to an inhibitory action of ovarian estrogen. Sex-dependent alterations of food consumption may cause the disparity between gastrin levels as male rats consumed a significantly greater amount of food over a 5-day analysis.

1618 RE-EVALUATION OF THE ROLE OF CYCLIC AMP IN HISTAMINE-INDUCED GASTRIC ACID SECRETION. (Eng.) Rosenfeld, G. C.; Jacobson, E. D.; Thompson, W. J. (Univ. Texas Medical Sch. Houston, Houston, TX 77025). *Gastroenterology* 70(5):832-835; 1976.

The relation between putative histamine H_2 receptors and gastric mucosal adenylyl cyclase and cyclic AMP phosphodiesterase was investigated in female Sprague Dawley rats. The 600 x *g* particulate fraction of gastric mucosal scrapings was incubated with ^3H-metiamide, which saturated available binding sites at a concentration of 1 μM. Scatchard plots showed a single component with a Kd value of 0.2 μM. Unlabeled cimetidine and histamine competed with ^3H-metiamide binding. The 600 x *g* particulate fractio also contained all of the hormone and sodium fluori sensitive adenylyl cyclase. Adenylyl cyclase activity was not altered by histamine, pentagastrin, or carbachol, each tested by wide concentration ranges (0.1-20 mM), but it was increased during incubation with prostaglandin E_1, secretin, and epinephrine. These findings do not support the hypothesis that gastric secretion is mediated by intracellular accumulation of cyclic AMP.

1619 ACTION OF H_1 AND H_2 INHIBITORS ON THE RESPONSE OF HISTAMINE SENSITIVE ADENYLYL

CYCLASE FROM GUINEA-PIG MUCOSA. (Eng.) Perrier, C. V.; Griessen, M. (Dept. Medicine, Univ. Geneva, Switzerland). *Eur. J. Clin. Invest.* 6(1):113-120; 1976.

The kinetics of burimamide, an H_2-inhibitor, and mepyramine and chlorpheniramine, both H_1-inhibitors, were studied in the adenylyl cyclase system. Adenylyl cyclase activity was assessed in homogenates of guinea pig fundic mucosa. The histamine content of this tissue was determined by a spectrofluorimetric method. Both H_1 and H_2 inhibitors behaved kinetically as competitive inhibitors of histamine, but the K_m derived for burimamide ($2.5\text{-}4.1 \times 10^{-5}$) was significantly lower than that for either chlorpheniramine ($0.9\text{-}1.9 \times 10^{-4}$) or mepyramine ($1.3\text{-}1.4 \times 10^{-4}$). However, none of the three inhibitors influenced the cyclase activation by prostaglandins 1 and 2. These results suggest that there are at least two types of receptors in the preparation studied, one responsive to histamine and the other to the prostaglandins. The specificity of H_1- and H_2-receptors is not absolute in the broken cell preparation.

1620 EXCITATION OF ACID AND PEPSIN SECRETION BY CHOLECYSTOKININ-PANCREOZYMIN IN PAVLOV AND HEIDENHAIN POUCHES OF THE RAT.

(Eng.) Lundell, L. (Inst. Physiology, Univ. Lund, Solvegatan 19, S-223 62 Lund, Sweden). *Experientia* 31(7):823-824; 1975.

The role of the vagus nerve for the sensitivity of the acid and pepsin secreting cells to cholecystokinin-pancreozymin (CCK-PZ) stimulation was studied in female Sprague-Dawley rats with Heidenhain or Pavlov pouches. CCK-PZ was infused i.v. for 90 min, and acid and pepsin outputs were measured. In the Heidenhain pouches, interdigestive acid secretion was 1.5 μEq/30 min and in the Pavlov pouches, it was 38.8 μEq/30 min. When CCK-PZ was infused in doses that caused maximal responses, the acid secretion rose to 71.7 μEq/30 min in the Heidenhain pouches and to 95.0 μE/30 min in the Pavlov pouches. The Pavlov pouch was more sensitive to CCK-PZ. Supramaximal doses of CCK-PZ caused a decrease in the secretory rate. Secretion with 2 μg/kg CCK-PZ was 63.8 μEq/30 min in the Pavlov pouches and 43.4 μEq/30 min in the Heidenhain pouches with 4 μg/hr of CCK-PZ. The interdigestive pepsin secretion was 115 μg/30 min in the Heidenhain pouches and 365 μg/30 min in the Pavlov pouches. CCK-PZ caused an increase to 347 μg/30 min with 0.25 μg/hr in the Heidenhain pouches and to 531 μg/30 min with 0.5 μg/hr in the Pavlov pouches. The results show that CCK-PZ is an effective stimulant of acid secretion in both types of rat pouches and that the vagus nerve facilitates the acid stimulatory potency of the drug.

1621 SECRETION OF HYDROCHLORIC ACID IN GHOSH-LAI RAT PREPARATION FOLLOWING STIMULATION WITH HISTAMINE AND PENTAGASTRIN AND INHIBITION BY GASTRONE AND ATROPINE.

(Eng.) Balanzo, J. T.; Glass, G. B. J. (New York Medical Coll., New York, NY 10029). *Digestion* 13(5):291-303; 1975.

The stimulatory effects of histamine and pentagastrin, and the inhibitory effects of gastrone and atropine, on the secretory output of HCl in Ghosh-Lai stomach preparation were quantitated in 48 successfully operated rats. The usefulness of this rat preparation was well demonstrated and good duplication of results was obtained with various doses of histamine and pentagastrin. The HCl output following an optimal i.v. pentagastrin dose of 6 μg/kg/30 min was almost twice that after an optimal i.v. histamine dose of 0.2 mg/kg/30 min. The inhibitory effect of gastrone B on histamine-stimulated HCl output was confirmed and was shown to extend also on the pentagastrin-stimulated HCl secretion. The comparison of the atropine and gastrone inhibition of the pentagastrin-stimulated HCl output in the Ghosh-Lai rat stomach preparation indicates that the inhibitory effect of 0.1 mg/kg atropine i.v. is less than that of 40 μg gastrone i.v., and that the effects of 0.4 mg/kg atropine i.v. are similar or slightly less than 50 μg gastrone i.v. The results demonstrate good applicability of this preparation to the quantification of acid secretion in the rat under basal conditions, after histamine or pentagastrin stimulation, and after the inhibition by gastrone and atropine.

1622 EFFECT OF METIAMIDE, A HISTAMINE H2-RECEPTOR ANTAGONIST, ON THE DEVELOPMENT OF GASTRIC STRESS ULCERS AND ACID SECRETION.

(Eng.) Bugajski, J.; Hano, J.; Danek, L. (Inst. Pharmacology, Polish Acad. Sciences, Krakow, Poland). *Eur. J. Pharmacol.* 36(1):237-240; 1976.

The effect of metiamide (0.0005-100 μM/kg), a histamine H2-receptor antagonist, on the development of gastric stress ulcers and acid secretion was investigated in Wistar rats. In normal and stressed rats with chronic gastric fistula, small doses (0.001-0.01 μM/kg) increased, and doses of over 20 μM/kg decreased, gastric acid secretion. In both of these dosage ranges, metiamide suppressed the development of stress ulcers, most markedly in doses of 0.005 and 100 μM/kg. Intermediate doses had no such action. Only the anti-ulcer action of large doses of metiamide paralleled a reduction in acid secretion. In normal and in stressed rats, neither of the anti-ulcer doses of metiamide (0.005 and 100 μM/kg) changed the level of biogenic amines in the brain. In the gastric wall, however, both doses of metiamide prevented a stress-induced fall of the noradrenaline (NA). In normal rats, metiamide consistently evoked a slight rise in the blood glucose level. During stress, doses greater than 0.001 μM/kg always reduced the observed hypoglycemia. The results indicate that histamine plays an essential role in the pathogenesis of stress ulcers, most probably as a mediator of the stimulation of gastric acid secretion. Metiamide, besides blocking the histamine H_2-receptor, also exhibits a weak adrenergic action.

LIBRARY U. OF I.

1623 GASTRIC MUCOSAL BLOOD FLOW AND PEPSIN SECRETION IN DOGS--STIMULATION BY 13-Nle-MOTILIN.

(Eng.) Koch, H.; Domschke, S.; Belohlavek, D.; Domschke, W.; Wunsch, E.; Jaeger, E.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nurnberg, D-852 Erlangen, Krankenhausstrasse 12, Munich, W. Germany). *Scand. J. Gastroenterol.* 11(1):93-96; 1976.

Gastric mucosal blood flow (GMBF) in response to graded doses of i.v. 13-norleucine-motilin (13-motilin) was studied in canine vagally denervated fundic pouches, using the aminopyrine clearance technique. As 13-nle-motilin did not exert any detectable effect on gastric secretion of hydrogen ions, intraluminal instillation of 160 mM HCl was used to provide a pH gradient allowing aminopyrine to move into the pouch lumen. With increasing doses of 13-nle-motilin, GMBF increased to 148% of control values; pepsin secretion, due to augmented pepsin concentration, rose concomitantly. Enhanced pepsin secretion was not accompanied by an increase in cyclic AMP secretion. These results indicate that aminopyrine clearance is increased by 13-nle-motilin, whereas H^+ secretion remains entirely unchanged. These data are consistent with reports demonstrating that primary changes in GMBF can be induced without affecting acid secretion, thus ruling out a strict causal relation between both parameters.

1624 INHIBITION OF STIMULATED GASTRIC SECRETION BY AN ORALLY ADMINISTERED PROSTAGLANDIN CAPSULE: A STUDY IN NORMAL MEN.

(Eng.) Wilson, D. E.; Quertermus, J.; Raiser, M.; Curran, J.; Robert, A. (840 South Wood St., Chicago, IL 60612). *Ann. Intern. Med.* 84(6):688-691; 1976.

The effect of ingestion of a gelatin capsule containing 127 μg of 16,16-dimethyl prostaglandin E_2 (DM-prostaglandin E_2) or a liquid containing 127 μg of DM-prostaglandin E_2 on stimulated gastric secretion was studied in 10 normal men. Forty-five min after the drug was administered, basal gastric secretion was collected. Submaximal gastric secretion was achieved by administering histamine acid phosphate (15 g/kg/hr, i.v.). Gastric secretion was collected by constant suction for 2 hr after the start of histamine infusion. Serum gastrin was measured just before ingestion of prostaglandin and 45 and 75 min after. DM-prostaglandin E_2 significantly reduced the volume, acid concentration, and total acid output of gastric secretion. Secretory inhibition during the 3 hr after treatment with the capsule was 37% (volume), 39% (acid concentration), and 60% (acid output). The DM-prostaglandin E_2 capsule was nearly as effective as an equivalent amount of DM-prostaglandin E_2 in solution. Prostaglandin analogues because of their oral effectiveness and duration of action may have therapeutic value in peptic ulcer disease.

1625 ON THE METABOLISM OF PROSTAGLANDINS BY HUMAN GASTRIC FUNDUS MUCOSA.

(Eng.) Peskar, B. M.; Peskar, B. A. (Medizinische Klinik, Univ. Freiburg, D-78 Freiburg i.Br., W. Germany). *Biochim. Biophys. Acta* 424(3):430-438; 1976.

Specific radioimmunoassays for the prostaglandins E_2, $F_{2\alpha}$, and A_2 and the metabolites 13,14-dihydro-15-keto-prostaglandin E_2, 15-keto-prostaglandin $F_{2\alpha}$, and 13,14-dihydro-15-keto-prostaglandin $F_{2\alpha}$ were used to study the metabolism of prostaglandins by gastroscopically obtained small biopsy specimens of human gastric fundus mucosa from 21 patients. Three prostaglandin-metabolizing enzymes were found in the 100,000 x *g* supernatant of human gastric fundus mucosa: 15-hydroxy-prostaglandin-dehydrogenase, Δ^{13}-reductase, and Δ^9-reductase. The specific activity was highest for 15-hydroxy-prostaglandin dehydrogenase and lowest for Δ^9-reductase. Formation of prostaglandin A_2 (or B_2) was not observed under the same conditions. None of the three enzyme activities detected in the 100,000 x *g* supernatant was found in the 10,000 x *g* and 100,000 x *g* pellets of human gastric fundus mucosa. The results indicate that high-speed supernatant derived from human gastric mucosa can rapidly metabolize prostaglandin E_2 and prostaglandin $F_{2\alpha}$ to the 15-keto and 13,14-dihydro-15-keto-derivatives. Furthermore, prostaglandin E_2 can be converted to prostaglandin $F_{2\alpha}$. The biological activity of prostaglandin $F_{2\alpha}$, on gastric functions, differs from that of prostaglandin E_2.

1626 INTERACTION OF PROSTAGLANDINS AND HISTAMINE WITH ENZYMES OF CYCLIC AMP METABOLISM FROM GUINEA PIG GASTRIC MUCOSA.

(Eng.) Wollin, A.; Code, C. F.; Dousa, T. P. (Mayo Clinic Foundation, Rochester, MN 55901). *J. Clin. Invest.* 57(6):1548-1553; 1976.

The effects of both prostaglandins (PGE_1, PGE_2, and PGA_1) and histamine were tested on the enzymes of cyclic AMP metabolism of the fundic and the antral gastric mucosa of the guinea pig. Both prostaglandins and histamine stimulated adenylate cyclase activity in cell-free membrane preparations of guinea pig gastric fundic mucosa. The stimulator effect of prostaglandins was specific and dose-dependent over a concentration range from 10^{-7} to 10^{-4} M. In similar preparations from antral regions of guinea pig gastric mucosa, the adenylate cyclase was stimulated only by PGE_1, PGE_2, and PGA_1 and not by histamine. Maximum stimulating doses of PGE_1, PGE_2, or PGA_1 (all 10^{-4} M), and of histamine (10^{-4} M) had an additive effect on the adenylate cyclase activity from fundic gastric mucosa. Metiamide (10^{-4} M) inhibited the stimulation of fundic mucosa adenylate cyclase by histamine but did not interfere with the stimulation by prostaglandins. Cyclic AMP phosphodiesterase activity of guinea pig gastric mucosa was unaffected by PGE_1 and PGE_2 or by histamine, and was slightly depressed by PGA_1. These results indicate that histamine and prostaglandins stimulate two different adenylate cyclase systems, both present in guinea pig gastric mucosa tissue. Therefore, the known inhibitory effect of prostaglandins on gastric acid secretion is not related to the interference with the stimulation of the histamine H_2-receptor-sensitive adenylate cyclase complex by histamine, nor do prostaglandins accelerate cyclic AMP breakdown by cyclic AMP phosphodiesterase to reduce cyclic AMP levels.

1627 **INHIBITION OF GASTRIC SECRETION IN THE DOG BY 16,16-DIMETHYL PROSTAGLANDIN E_2.** (Eng.) Mihas, A. A.; Gibson, R. G.; Hirschowitz, B. I. (Div. Gastroenterology, Univ. Alabama, Birmingham, AL 35294). *Am. J. Physiol.* 230(2):351-356; 1976.

The action of a synthetic derivative of prostaglandin E_2, 16,16-dimethyl prostaglandin E_2 methyl ester (16,16-dimethyl PGE_2 methyl ester), was investigated in four dogs. The synthetic prostaglandin given by i.v. infusion (0.4 μg/kg/hr) inhibited gastric secretion of H^+, K^+, Cl^-, and pepsin in the four fistula dogs stimulated by histamine (H, 2-100 μg/kg/hr), pentagastrin (P, 0.1-5 μg/kg/hr), urecholine (U, 20-160 μg/kg/hr), and 2-deoxy-D-glucose (2-DG, 100 mg/kg, 10 min). During steady infusions of near-maximal doses of H, P, and U, PG-E_2 caused 75% inhibition of H^+ maximally at 90 min and over 85% inhibition of pepsin secretion maximally at 45 min. Recovery of secretion occurred 1-2 hr after infusion of PGE_2 was stopped. Injection of KCl, 1 mEq/kg, during inhibition of histamine by PGE_2 gave only a 15-min transient reversal of inhibition. When PGE_2 was given as background to 45-min step-dose responses, 0.1 μg/kg competitively inhibited histamine stimulation and 0.4 μg/kg/hr gave 100% inhibition. Against pentagastrin, 0.1 μg PGE_2/kg/hr had no effect and 0.4 μg caused uncompetitive inhibition; against urecholine, 0.4 μg PGE_2/kg/hr caused competitive inhibition of H^+ secretion. Pepsin was more markedly inhibited in each case. There were no side effects at either dose of PGE_2, which is a potent inhibitor of gastric secretion with all forms of stimuli.

1628 **THE INTERACTION OF SECRETIN AND STIMULANTS OF GASTRIC ACID SECRETION IN ANAESTHETIZED CATS.** (Eng.) Braganza, J. M.; Gibbs, A. C. C.; Howat, H. T. (Manchester Royal Infirmary, Manchester M13 9WL, England). *J. Physiol. (London)* 258(1):73-81; 1976.

Acid secretion in response to cerulein (2.5-20 ng/kg/min), desulfated cerulein (20-100 ng/kg/min), histamine (375-1,500 ng/kg/min), and N-methyl histamine (375-3,000 ng/kg/min), given alone or combined with Boots secretin 4 C.H.R. U/kg/hr, was studied in fasting anesthetized cats in which the pylorus and common bile duct were occluded. Eight separate estimates of the calculated maximal response of acid (four acid stimulants given with and without secretin) did not differ significantly from one another. In the presence of secretin, the ED_{50} of each acid stimulant was decreased. Outputs of acid in response to the smallest doses of desulfated cerulein, histamine, and N-methyl histamine increased significantly when secretin was infused ($p<0.5$). On a weight basis, cerulein was 23, 474, and 95 times more potent than desulfated cerulein, histamine, and N-methyl histamine, resp. When secretin was infused simultaneously, cerulein was 8, 171, and 165 times more potent than desulfated cerulein, histamine, and N-methyl histamine, resp. N-methyl histamine was 5.6 times more potent than histamine on a weight basis when infused alone; it was 1·16 times more potent than histamine when given in the presence of secretin. Boots secretin enhanced the acid response to the four acid stimulants. The authors suggest that Boots secretin contains an additional peptic stimulant other than secretin itself that contributes significantly to the pepsin stimulating activity of the preparation in cats.

1629 **COMPARISON OF VASOACTIVE INTESTINAL PEPTIDE (VIP) AND SECRETIN IN GASTRIC SECRETION AND MUCOSAL BLOOD FLOW.** (Eng.) Konturek, S. J.; Dembinski, A.; Thor, P.; Krol, R. (Inst. Physiology, 31-531 Krakow, ul. Grzegorzecka 16, Poland). *Pfluegers Arch.* 361(2):175-181; 1976.

The effects of vasoactive intestinal peptide (VIP) and secretin on gastric acid and pepsin secretion induced by pentagastrin, histamine, or a peptone meal, as well as the effects on gastric mucosal blood flow and meal-induced serum gastrin level, were compared in three conscious dogs, which were provided with gastric fistulas and denervated fundic pouches. Both VIP and secretin caused a dose-related stimulation of basal pepsin outputs and inhibition of pentagastrin-induced acid secretion. A dose of 8 μg/kg VIP or 1 U/kg secretin caused about 50% inhibition of pentagastrin-induced half-maximal acid output. VIP (8 μg/kg/hr), like secretin (1 U/kg/hr), inhibited pentagastrin (2 μg/kg-hr) and meal-induced gastric acid secretion, but in contrast to secretin, it caused inhibition of acid response to histamine (80 μg/kg/hr). Inhibition of acid secretion by VIP or secretin was accompanied by secondary reduction in gastric mucosal blood flow in tests with pentagastrin or histamine and by depression of the serum gastrin level in tests with a 10% peptone meal. This study indicates that in comparison with secretin, VIP has a wider spectrum of inhibition of stimulated gastric secretion and it may be considered as one of the enterogastrones released in the small intestine.

SECRETION AND METABOLISM

Pancreas

1641 THE EFFECT OF CHRONIC INTRAGASTRIC ALCOHOL INGESTION ON THE PANCREATIC SECRETION OF THE RAT. (Eng.) Huttunen, R.; Huttunen, P.; Jalovaara, P. (Univ. Central Hosp. Oulu, 90220 Oulu 22, Finland). *Scand. J. Gastroenterol.* 11(1):103-106; 1976.

The effect of chronic intragastric ethanol ingestion on pancreatic secretion was studied in Long Evans rats. The rats received 20% alcohol (1 ml/ 0.1 kg) by gastric intubation 5 times weekly, and the total duration of ingestion was 10-12 weeks. Pancreatic juice was collected by cannulating the pancreatic duct under ether anesthesia; basal secretion was collected during 15 min after which a further 15-min secretion was stimulated with pancreozymin (0.15 U). The volume and the content of proteins, proteolytic enzymes, and trypsin inhibitors were studied. The secretion of proteins decreased significantly, while the amount of active proteolytic enzymes was increased in the pancreatic secretion of the rats given alcohol. No active trypsin was noted in either group. The amount of trypsin inhibitors decreased in the pancreatic juice of the rats given alcohol compared with that of the control rats, but the decrease was relative to the decrease in the secretion of total proteins. No significant differences were noted in the volume of the secreted pancreatic juice between the experimental rats and the control rats. Pancreozymin increased the secretion about twofold, and the response to pancreozymin was similar in the two groups. Thus, the results demonstrate that chronic alcoholic ingestion affects pancreatic secretion of rats.

1642 PREMATURE INDUCTION OF AMYLASE IN PANCREAS AND PAROTID GLAND OF GROWING RATS BY DEXAMETHASONE. (Eng.) Sasaki, R.; Mura, M.; Takeuchi, T. Furihata, C.; Matsushima, T.; Sugimura, T. (Inst. Medical Science, Univ. Tokyo, Minato-Ku, Tokyo 108, Japan). *Biochim. Biophys. Acta* 428(3):619-626; 1976.

Studies were made on changes in the contents of α-amylase in the pancreas and parotid gland of Wistar-Imamichi rats during postnatal development. In addition, premature induction of this enzyme by hormones, and the existence of specific glucocorticoid receptors in these tissues were also studied. Amylase activity was determined by the blue-starch method in supernatants of tissue homogenates centrifuged at 20,000 x *g*. Specific glucocorticoid receptors were measured by the binding of the synthetic glucocorticoid dexamethasone to the soluble fractions of pancreas and parotid gland. The amylase content in the pancreas increased from the 9th day after birth and reached the adult level on the 28th day; its content in the parotid gland increased rapidly from the 16th to 28th day after birth and then rose more gradually to the adult level. Injection of dexamethasone (0.1 or 1 mg/kg, s.c.) into rats, 6-8 days after birth induced an increase in the amylase of the pancreas but not that of the parotid gland. However, injection of dexamethasone into weanling rats 21-23 days after birth resulted in precocious induction of amylase in both tissues. Specific glucocorticoid receptors were detectable in the parotid gland of rats from 6 days after birth, but they were almost undetectable in the pancreas until adolescence. These results indicate that the response to dexamethasone is not correlated with the level of specific glucocorticoid receptors.

1643 EFFECTS OF SOMATOSTATIN ON EXOCRINE AND ENDOCRINE PANCREATIC FUNCTION STIMULATED BY INTESTINAL HORMONES IN MAN. (Eng.) Dollinger, H. C.; Raptis, S.; Pfeiffer, E. F. (Zentrum f. Innere Medizin und Kinderheilkunde, Universitat Ulm, D-79 Ulm/Do., Steinhovelstr., 9, Germany). *Horm. Metab. Res.* 8(1):74-78; 1976.

To evaluate the action of somatostatin on exocrine and endocrine pancreatic function, a 300 μg bolus of synthetic somatostatin (GIF) was administered i.v. to 17 normal subjects. This was followed by a constant 60-min infusion (5 μg/min). Secretin-induced (0.25 U/kg/hr) volume and total bicarbonate contents of the duodenal aspirate were not affected by GIF, whereas the bicarbonate concentration was significantly diminished. GIF reduced the pancreatic enzyme secretion stimulated by pure (99%) cholecystokinin-pancreozymin. After the GIF infusion was stopped, a significant rise in enzyme secretion was observed. The secretin-induced insulin release was almost completely suppressed. Because GIF can be extracted in large quantities from pancreas, these data suggest that somatostatin may play a physiological role in the regulation of the secretory processes of this organ. Furthermore, the ability of GIF to inhibit circulating plasma gastrin and gastric secretion as well as to reduce requirements for exogenous insulin makes it a potentially useful adjunct in the treatment of acute pancreatitis.

1644 EXTERNAL PANCREATIC SECRETION AFTER BOMBESIN INFUSION IN MAN. (Eng.) Basso, N.; Giri, S.; Improta, G.; Lezoche, E.; Melchiorri, P.; Percoco, M.; Speranza, V. (Istituto III Patologia Chirurgica, Policlinico Umberto I. Universita di Roma, Rome, Italy). *Gut* 16(12):994-998; 1975.

The effect of bombesin on external pancreatic secretion was studied in seven healthy volunteers and in two patients with a two-thirds gastrectomy and a pancreatic fistula. After an i.v. 90-min infusion of bombesin (15 ng/kg/min), gastrin levels were significantly raised in all volunteers, but they remained at basal levels in the gastrectomized patients. Bombesin stimulated pancreatic secretion in all patients. The volume of secretion increased twofold when compared with basal volume. Amylase and trypsin concentrations and outputs in the duodenal juice were greatly augmented (basal amylase concentration, 70 dye U/ml; post-bombesin, 620 dye U/ml; basal amylase output, 1,000 dye U/15 min; post-bombesin, 15,800 dye U/15 min). When administered in conjunction with bombesin, secretin (1.7 U/kg/hr) partially inhibited its secretory effect. Bicarbonate secretion was slightly stimulated by bombesin, but at a very low level. A similar pattern of results was obtained in the two gastrectomized patients. This study confirms that bombesin greatly stimulates gastric secretion and exerts an effect on pancreatic secretion that mimics the effect of cholecystokinin-pancreozymin (CCK-PZ); the latter may be related to a direct CCK-PZ-like effect of bombesin on the pancreas or to the release of CCK-PZ from the duodenum due to the bombesin. Gastrin release does not play a fundamental role in this phenomenon.

SECRETION AND METABOLISM

Hepatobiliary Tract

1651 EXPIRATORY MEASUREMENT OF MAXIMAL AMINOPYRINE DEMETHYLATION IN VIVO: EFFECT OF PHENOBARBITAL, PARTIAL HEPATECTOMY, PORTACAVAL SHUNT AND BILE DUCT LIGATION IN THE RAT. (Eng.) Lauterburg., B. H.; Bircher, J. (Mayo Graduate Sch. Medicine, Rochester, MN). *J. Pharmacol. Exp. Ther.* 196 (2):501-509; 1976.

Experiments were undertaken to estimate the drug-metabolizing capacity (V_{max}) and the dose yielding affinity $V_{max}/2$(Kd) from demethylation rates, measured by $^{14}CO_2$ exhalation in Wistar rats. Various doses of ^{14}C-aminopyrine were injected i.v. to unanesthetized rats. Drug clearances based on $^{14}CO_2$ exhalation agreed well with those derived from plasma disappearance rates. Evaluation of dose-response curves revealed saturation phenomena. In the normal rat, a V_{max} of 173 nmol/min/100 g and a K_d of 26 μmol/100 g were calculated. Enzyme induction with phenobarbital increased V_{max} to 745 nmol/min/100 g, whereas in the rat with portacaval shunt, it was reduced to 45 nmol/min/100 g. After 48-hr bile duct ligation, V_{max} was not significantly different from the controls, but K_d increased to 36 μmol/100 g, compatible with a competitive type of inhibition of aminopyrine demethylation. Two-thirds hepatectomy reduced V_{max} by only 50%, suggesting that a substantial portion of demethylation occurs extrahepatically. This appears to be a valid alternative to conventional plasma clearance methods, allowing interpretation of some mechanisms affecting *in vivo* drug metabolism under various conditions.

1652 COMPARTMENTATION OF ALBUMIN AND FERRITIN SYNTHESIS IN RAT LIVER IN VIVO. (Eng.) Fern, E. B.; Garlick, P. J. (Dept. Biochemistry, Univ. Wisconsin, Madison, WI 53706). *Biochem. J.* 156(1):189-192; 1976.

Further evidence of cellular compartmentation of aminoacyl-transfer RNA was obtained by comparing the specific radioactivity of serine with that of glycine in albumin and ferritin in 12 rat livers. Although the specific radioactivities of free glycine and serine rose between 3-6 hr of [U-^{14}C]glycine infusion, their ratio (serine/glycine) remained constant. The specific radioactivity ratio in total liver protein was also constant and much closer to that of the free amino acids in liver than in either arterial or hepatic portal plasma. With albumin, the specific radioactivity ratio was better related to the free pool in liver than to that in either plasma. These results suggest that the precursor pool for protein synthesis is more directly related to intracellular amino acids than to those in plasma. In both normal rats and rats in which ferritin synthesis had been previously induced with an s.c. injection of 10 mg of iron sorbitol, the specific radioactivity ratio in the liver ferritin was very close to that in the total liver protein, whereas, in albumin it was lower. The results suggest that albumin and ferritin are not synthesized from the same pool of free amino acids.

1653 ETHANOL--A DIRECT INDUCER OF DRUG METABOLISM. (Eng.) Kalant, H.; Khanna, J. M.; Lin, G. Y.; Chung, S. (Dept. Pharmacology, Univ. Toronto, Toronto, Ontario, Canada). *Biochem. Pharmacol.* 25(3):337-342; 1976.

The inductive effects of chronic phenobarbital and ethanol ingestion on hepatic microsomal drug metabolism were examined in Wistar rats which consumed different proportions of dietary fat. Eight groups of rats were fed for 1 week on matched amounts of nutritionally adequate liquid diets providing 2, 5, 10, or 41% of calories as fat (safflower oil); 2 groups were at each level. One group at each level received phenobarbital (80 mg/kg daily by intubation); the other received water. In a parallel experiment, 1 group at each fat level received 36% of calories as ethanol, the other as sucrose, and these regimens were continued for 1 month. Dietary fat content had no significant effect on body weight, liver weight, microsomal protein, cytochrome P-450 content, or hepatic triglycerides (TG) during the 1-week experiment, but it significantly increased all these measures in the 1-month experiment. Both phenobarbital and ethanol treatment increased all these measures except body weight. Phenobarbital had a greater effect on liver weight, microsomal protein, and cytochrome P-450, while ethanol had a greater effect on hepatic TG and a significant interaction with dietary fat content in relation to TG levels. In contrast, microsomal metabolism of aminopyrine, aniline, and meprobamate *in vitro* was increased almost equally by phenobarbital and ethanol, while dietary fat content had no effect alone, and no significant interaction with phenobarbital or ethanol. Ethanol, like phenobarbital, therefore, appears to induce microsomal drug metabolism independently of its effects on TG metabolism.

1654 MECHANISMS OF INCREASED α_1-FETOPROTEIN PRODUCTION IN HEPATIC INJURY. (Eng.)

Watanabe, A.; Miyazaki, M.; Taketa, K. (Okayama Univ. Medical Sch., 5-1, 2-chome, Shikata-cho, Okayama 700, Japan). *Experientia* 32(4):470-471; 1976.

The association of increased serum α_1-fetoprotein (AFP) and increased DNA synthesis seen in liver damage was investigated in 35-day-old Sprague-Dawley rats given an i.p. injection of thioacetamide (5 mg/100 g) or DL-ethionine (100 mg/100 g). Administration of ATP to ethionine-treated rats inhibited the rise in serum AFP and liver damage (triglyceride content and glucose-6-phosphate dehydrogenase). The low dose of thioacetamide caused neither any evidence of liver cell injury nor increased production of AFP, even in the presence of accelerated DNA synthesis. Thus, the increased production of AFP in injured liver is primarily associated with hepatic injury and not with liver cell regeneration.

1655 INFLUENCE OF PYRAZOLE ON HEPATIC [1-^{14}C] PALMITATE OXIDATION DURING ACUTE ETHANOL INTOXICATION. (Eng.)

Beauge, F.; Clement, M.; Nordmann, J.; Nordmann, R. (Hopital de la Salpetriere, 47, Boulevard de l'Hopital-75013 Paris, France). *Biomedicine* [*Express*] 25(2):70-71; 1976.

The effects of pyrazole on alcohol-induced inhibition of hepatic palmitate oxidation were studied in female Wistar rats. Pyrazole (272 mg/kg, i.p.) was injected 10 min before ethanol intubation (4 mg/kg). Liver slices were then incubated with 1-^{14}C-palmitic acid, and the evolved $^{14}CO_2$ was estimated. Pyrazole reduced, but did not completely suppress, the inhibition of palmitate oxidation 1.5 hr after ethanol administration, and it failed to affect this inhibition significantly 4 hr after intubation. At 20 hr after intubation, there were no disturbances of palmitate oxidation, and at 30 hr, there was a significant ($p<0.01$) inhibition of palmitate oxidation in rats treated with pyrazole, confirming the relation between active ethanol metabolism and inhibition of fatty acid oxidation. It is concluded that pyrazole is not a convenient agent for studying the mechanisms of fatty liver induction or the role of decreased fatty acid oxidation by ethanol.

1656 MEASUREMENT OF BILE ACID SYNTHESIS BY $^{14}CO_2$: THE METABOLISM OF PROPIONYL CoA.

(Eng.) Davis, R. A.; Showalter, J. P.; Kern, F., Jr. (Univ. Colorado Medical Center, Denver, CO 80220). *Steroids* 26(4):408-421; 1975.

The relation between $^{14}CO_2$ evolution from the catabolism of [26 or 27^{14}C]cholesterol to bile acids was studied in female Sprague-Dawley rats with biliary fistulae. When equal quantities of [26 or 27^{14}C]-cholesterol and [4^{14}C]cholesterol were administered, there was a significant linear relationship between $^{14}CO_2$ expiration in the breath and [4^{14}C] bile acid excretion in the bile. Bile acid synthesis calculated as the ratio of $^{14}CO_2$ to molar specific activity of biliary cholesterol correlated highly with biliary bile acid excretion in the bile acid-depleted rat. Phenobarbital (80 mg/kg/day, 7 days, i.m.) did not alter the relation between the $^{14}CO_2$ estimation of bile acid synthesis and biliary bile acid excretion, indicating that the relation between [26 or 27^{14}C]-cholesterol side chain cleavage and $^{14}CO_2$ formation was not altered. Phenobarbital did cause a reduction in bile acid synthesis, as measured by $^{14}CO_2$ evolution and by biliary bile acid excretion. The $^{14}CO_2$ method underestimated bile acid synthesis by 12.2 and 8.7% in untreated and phenobarbital treated rats, resp. Since 11% of the radioactivity, expired as $^{14}CO_2$, was isolated as bile acids, radioactivity cleaved as [1 or 3^{14}C]propionyl coenzyme A (CoA) may enter cholesterol-bile acid biosynthesis resulting in the underestimation of bile acid synthesis. To determine whether radioactivity from propionyl CoA enters steroid biosynthesis, [1^{14}C]propionate and [2^{14}C]propionate (3.5 μCi) were injected i.p. in untreated biliary fistula rats, and the biliary lipids excreted after 60 hr were analyzed. Incorporation of radioactivity into cholesterol and bile acids was greater after the administration of [2^{14}C]-propionate than after [1^{14}C]propionate, suggesting that radioactivity from propionyl CoA may enter steroid biosynthesis by metabolic events in which the methylene and carboxyl carbon atoms are differentiated. Although the use of $^{14}CO_2$ expiration from [26 or 27^{14}C]cholesterol catabolism under-

LIBRARY U. OF I. URBANA-CHAMPAIGN

estimates the rate of bile acid synthesis, it should have many applications because of the constant relation between $^{14}CO_2$ formation and cholesterol side chain cleavage.

1657 FORMATION OF BILE ACIDS IN MAN. METABOLISM OF 7α-HYDROXY-4-CHOLESTEN-3-ONE IN NORMAL SUBJECTS WITH AN INTACT ENTEROHEPATIC CIRCULATION.

(Eng.) Hanson, R. F.; Szczepanik, P. A.; Klein, P. D.; Johnson, E. A.; Williams, G. C. (Gastroenterology Unit, Univ. Minnesota, Minneapolis, MN 55455). *Biochim. Biophys. Acta* 431(2): 335-346; 1976.

The metabolism of labeled 7-alpha-hydroxy-4-cholesten-3-one (HCO) was investigated in eight normal subjects with intact enterohepatic circulation to determine whether the entire production of cholic acid and chenodeoxycholic acid takes place via HCO. In six of eight subjects, the area under the cholic acid specific activity decay curve was significantly less than the area under the chenodeoxycholic acid specific activity decay curve, indicating that the entire production of cholic acid and deoxycholic acid does not take place via HCO. The production rates ranged from 0.49 to 1.18 nmol/day for cholic acid and 0.64 to 1.20 nmol/day for chenodeoxycholic acid. The fraction of the injected ^{3}H-labeled HC metabolized to cholic acid and chenodeoxyxholic acid was calculated in these six subjects at 0.51 for cholic acid and at 0.55 for chenodeoxycholic acid. These results show that the production of cholic acid in man may not always involve the intermediate 7-alpha hydroxy-4-cholesten-3-one.

1658 INFLUENCE OF CHOLESTEROL FEEDING ON LIVER MICROSOMAL METABOLISM OF STEROIDS AND BILE ACIDS IN CONVENTIONAL AND GERM-FREE RATS.

(Eng.) Gustafsson, B. E.; Einarsson, K.; Gustafsson, J. A. (Karolinska Institutet, Stockholm, Sweden). *J. Biol. Chem.* 250(21):8496-8502; 1975.

The factor responsible for the differences in microsomal metabolism of steroids between germ-free and conventional rats was investigated. A diet containing 0.4% (weight/weight) cholesterol, cholic acid, taurocholic acid, and chenodeoxycholic acid was fed to conventional and germ-free male rats, and the effect on liver microsomal metabolism of 4-[4-^{14}C]androstene-3,17-dione, 5α[4-^{14}C]androstane-3α,17β-diol, [4-^{14}C]cholesterol, 7α-hydroxy-4-[6β-^{3}H]cholesten-3-one, and [24-^{14}C]lithocholic acid was studied. The most consistent effects were found with dietary cholesterol. It stimulated the activities of several of the hydroxylases active on 4-androstene-3,17-dione and 5α-androstane-3α,17β-diol; it decreased the 5α reduction of 4-androstene-3,17-dione; it increased the 7α hydroxylation of cholesterol; it decreased the 12α hydroxylation of 7α-hydroxy-4-cholesten-3-one; and it increased the hydroxylation of lithocholic acid by 6β. These effects of cholesterol feeding on the microsomal metabolism of steroids in conventional rats made the pattern of microsomal enzyme activities resemble that characteristic of germ-free rats. Cholesterol feeding led to a pronounced increase in the intestinal concentration of β-muricholic acid in conventional rats. Cholesterol feeding to conventional animals led to an intestinal ratio of chenodeoxycholic acid (including its metabolites α- and β-muricholic acid and hyodeoxycholic acid) to cholic acid (including deoxycholic acid) that was almost identical to that in germ-free rats. Conventionalization of germ-free rats for a period of up to 56 days led only to a partial normalization of the liver microsomal metabolism of 5α-[4-^{14}C]androstane-3α,17β-diol and 7α-hydroxy-4-[6β-^{3}H]cholesten-3-one and of the liver microsomal concentration of cytochrome P-450. The concentration of cholesterol was higher in both total liver homogenate and liver microsomal fraction of germ-free rats than in corresponding preparations from conventional rats. It is suggested that cholesterol is one of the factors responsible for the different microsomal metabolism of steroids in germ-free and conventional rats. It is also suggested that cholesterol may play a role as regulator of microsomal enzyme activities.

1659 INHIBITORY EFFECTS OF SCILLAREN AND DINITROPHENOL ON BILIRUBIN EXCRETION BY THE ISOLATED PERFUSED RAT LIVER.

(Eng.) Bloomer, J. R.; Zaccaria, J.; Klatskin, G. (Yale Univ. Sch. Medicine, 33 Cedar St., New Haven, CT 06510). *Proc. Soc. Exp. Biol. Med.* 151(3):539-542; 1976.

The effects of scillaren (a mixture of cardioactive glycosides from fresh squill) and dinitrophenol on bilirubin excretion by the perfused Wistar rat liver were studied. Ninety milliliters of perfusing medium, consisting of sheep RBC, 3 g/100 ml bovine albumin, and 100 mg/100 ml glucose, were perfused at 20 ml/min for 3 hr. Bilirubin was infused into the medium at 18.8 μg/min/g of liver or 7.9 μg/min/g 30 min after the perfusion was initiated. Sodium taurocholate (30 μmol/hr) was infused simultaneously, and 60 min later, either 25 mg of scillaren or 16.6 mg of 2,4-dinitrophenol was added to the perfusing medium. Both compounds inhibited bile flow, scillaren by 20-40% and dinitrophenol by 60-80%. Bilirubin excretion was also impaired. However, the effect of scillaren on bilirubin excretion was less than that on bile flow, as indicated by an increase in the bile bilirubin concentration. Dinitrophenol had a greater effect on bilirubin excretion than on bile flow. Dinitrophenol also inhibited the hepatic removal of unconjugated bilirubin from the perfusate, probably because it impaired the initial uptake and/or storage of unconjugated bilirubin by the perfused liver.

1660 HEPATOCELLULAR TRANSPLANTATION FOR METABOLIC DEFICIENCIES: DECREASE OF PLASMA BILIRUBIN IN GUNN RATS.

(Eng.) Matas, A. J.; Sutherland, D. E. R.; Steffes, M. W.; Mauer, S. M.; Lowe, A.; Simmons, R. L.; Najarian, J. S. (Dept.

Surgery, Univ. Minnesota, Minneapolis, MN 55455). *Science* 192(4242):892-894; 1976.

Hepatocytes from heterozygous Gunn rats were transplanted in homozygous recessive Gunn rats, which had a uridine diphosphate glucuronyltransferase deficiency, to develop a hepatocellular transplantation method that could be used in human enzyme deficiency diseases. All recipients received 100 U of sodium heparin s.c. 1 hr preoperatively and rabbit antiserum to rat lymphocytes for 12 weeks postoperatively. In eight rats receiving hepatocellular transplants via the portal vein, concentrations of bilirubin fell gradually, and after 3 weeks, postoperative values were significantly lower than preoperative values; this effect lasted for 30 weeks in two animals. Similar results were obtained in a second series of experiments, in which the alkaline azobilirubin blue reaction was used to measure bilirubin (preoperative, 10.45 mg/100 ml; 5 weeks postoperative, 5.5 mg/100 ml, $p<0.01$). No significant differences in bilirubin levels were seen in eight rats receiving Hanks solution through the portal vein, in five rats receiving spleen cells via the portal vein, or in four rats receiving hepatocytes dispersed in the peritoneal cavity. The results indicate that hepatocellular transplantation provides the missing enzyme in these rats. It is concluded that this method may be applicable to human congenital enzyme deficiency disease.

1661 THE INFLUENCE OF DIET ON UNCONJUGATED HYPERBILIRUBINAEMIA IN THE GUNN RAT.

(Eng.) Gollan, J. L.; Hatt, K. J.; Billing, B. H. (Royal Free Hosp., Pond St., Hampstead, London NW3 2QG, England). *Clin. Sci. Mol. Med.* 49(3):229-235; 1975.

The influence of dietary carbohydrate, protein, and lipid on the unconjugated hyperbilirubinemia of Gunn rats was studied. After a control period without restraint, animals were restrained for 72 hr and were either starved or given isocaloric amounts of glucose, protein hydrolysate, or soybean oil through a gastrotomy cannula. A second study was performed with groups of unrestrained animals that were fed with diets supplemented with carbohydrate, protein, and lipid for 7 days after a control period. Both studies showed that diets composed predominantly of carbohydrate or protein doubled the plasma bilirubin concentration. Starch, glucose, and fructose produced similar effects. A high-lipid diet in the absence of carbohydrate caused a slight reduction in plasma bilirubin concentration. This effect was observed with both soybean oil and pork fat. The findings do not indicate whether the increase in hyperbilirubinemia resulted from the high carbohydrate content of the diet or from the absence of lipid.

1662 PATHOGENESIS OF COPPER DEPOSITION IN LIVER CELLS.

(Eng.) Iyenegar, B. (B-72 Pandra Rd., New Delhi-3, India). *Acta Morphol. Acad. Sci. Hung.* 22(2):169-175; 1974.

Copper deposition in the rat liver was studied after the intracardiac injection of copper sulfate (2 μg/100 g). Copper deposition in the hepatocytes increased gradually, reaching a peak after 5 days. An intense, diffuse deposition was seen in the cytoplasm, the area of the cell membrane, nuclear membrane, and the chromatin. Thus, the sinusoids of the liver passed the bound copper directly to the hepatocytes. After 7 days, the deposition was restricted to the centrilobular cells; there was also a dense deposition in the Kupffer cells, which had previously shown little or no deposition. The apparent transfer of copper from the hepatocytes to the Kupffer cells indicates that the removal of copper by the Kupffer cells protects the hepatocytes from the prolonged action of copper.

1663 THE CAPABILITY FOR HORMONE-STIMULATED ENZYME ADAPTATION IN LIVER CELLS ISOLATED FROM AGING RATS.

(Eng.) Britton, G. W.; Britton, V. J.; Gold, G.; Adelman, R. C. (Philadelphia Coll. Osteopathic Medicine, Philadelphia, PA). *Exp. Gerontol.* 11(1/2):1-4; 1976.

Hepatocytes isolated from male Sprague-Dawley rats aged 2-24 months were incubated with hydrocortisone to determine whether the resulting increase in tyrosine aminotransferase varied with age. When the hepatocytes were incubated up to 5 hr with 2.1 x 10^{-5} M hydrocortisone, both time course and magnitude of the increased tyrosine aminotransferase activity were identical for 2- and 24-month old rats. These data support the concept that previously documented age-dependent changes in liver enzyme adaptation probably reflect alterations in extrahepatic regulatory mechanisms.

1664 CHANGES IN CATECHOLAMINE- AND GLUCAGON-RESPONSIVE ADENYLATE CYCLASE ACTIVITY IN PRENEOPLASTIC RAT LIVER.

(Eng.) Boyd, H.; Martin, T. J. (Univ. Miami Sch. Medicine, Miami, FL 33152). *Mol. Pharmacol.* 12(2):195-202; 1976.

Pharmacological studies of adenylate cyclase activation were undertaken in preneoplastic rat liver with respect to alpha and beta adrenergic receptors and glucagon receptors. Increases in basal and catecholamine-responsive adenylate cyclase activity were observed in the livers of Sprague-Dawley rats treated with 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB, 0.06% in diet, 1-12 weeks). These increases were accompanied by a decrease in glucagon responsiveness of the enzyme. Binding of 3'-MeDAB metabolites reached a peak at 3 weeks, considerably earlier than the peak increases in adenylate cyclase activity at 6 weeks. By the time tumors were detected in the tissue (10-20 weeks), adenylate cyclase activity and response to catecholamine stimulation were back to or below normal. The greatly increased stimulation of adenylate cyclase activity by catecholamines was a beta receptor effect; however, inhibition of the enzyme by catecholamines was also seen when there was elevated basal activity, and

LIBRARY U. OF I. URBANA-CHAMPAIGN

this may be an alpha adrenergic effect. The fact that glucagon and catecholamine effects are additive at certain concentrations of catecholamine, but only partially so at others, indicates that the two receptor-cyclase systems are not entirely separate. The preneoplastic rat liver appears to be a suitable tissue to study hormone-receptor interactions at both molecular and physiological levels. It was the first broken cell preparation in which inhibitory effects of catecholamines on adenylate cyclase activity were observed.

1665 RATES OF INDUCTION OF MITOCHONDRIAL ALDEHYDE DEHYDROGENASE IN RAT LIVER. (Eng.) Horton, A. A.; Barrett, M. C. (Dept. Biochemistry, Univ. Birmingham, P.O. Box 363, Birmingham B15 2TT, U.K.). *Biochem. J.* 156(1):177-179; 1976.

The rate of induction of aldehyde dehydrogenase activity was studied in liver mitochondria isolated from female Wistar rats which were given ethanol (25% weight/volume, 2 ml portions) by gastric intubation at hourly intervals up to 5 hr. There was an initial lag period of nearly 1 hr followed by a rapid increase in aldehyde dehydrogenase specific activity until a maximum was attained at 3 hr. Aldehyde dehydrogenases from control rats, given a quantity of glucose that was isocaloric with the ethanol, showed no change in specific activity. It is concluded that the rapid increase in specific activity of mitochondrial aldehyde dehydrogenase is a response to the increased concentrations of acetaldehyde resulting from the higher rate of oxidation of ethanol, and it probably constitutes a protective mechanism for the removal of acetaldehyde.

1666 THE REGULATION OF 3-HYDROXY-3-METHYLGLUTARYL COENZYME A REDUCTASE IN THE ISOLATED PERFUSED RAT LIVER. (Eng.) Cooper, A. D. (Stanford Univ. Sch. Medicine, Stanford, CA 94305). *J. Clin. Invest.* 57(6):1461-1470; 1976.

To determine the sterol component(s) of bile that primarily regulates the rate of hepatic cholesterol synthesis, the effect of perfusion of an isolated Sprague-Dawley rat liver on hepatic 3-hydroxy-3-methylglutaryl coenzyme A reductase was studied. In liver removed during the basal period of the diurnal cycle of enzyme activity, a 227 ± 41% increase in enzyme activity occurred after 3 hr of a plasma-free perfusion. The addition of cycloheximide or pure cholesterol (dispersed with lecithin) to the perfusate prevented this increase in enzyme activity. In contrast, the continuous addition of taurocholate or taurochenodeoxycholate, alone or in combination, at a variety of rates did not prevent the increase in enzyme activity. The added bile salts were efficiently extracted from the perfusate and were excreted in the bile. The addition of these bile salts to a cholesterol-enriched perfusate did not alter the effect obtained with cholesterol alone. If the perfusate contained whole serum, the increase induced by perfusion in the basal period was smaller (88 ± 27%) than with plasma-free perfusate. Again, the major bile salts of the rat failed to prevent the increase in enzyme activity induced by liver perfusion. If livers were removed and perfused at the height of the diurnal cycle of enzyme activity, the enzyme activity remained high (2 ± 10% increase) rather than decreasing, as occurs *in vivo*. If cholesterol was added to these perfusions, a 52 ± 4% decrease was induced. Bile salt addition induced no decrease. It is concluded that the major bile salts are not direct regulators of hepatic cholesterol synthesis, but pure cholesterol, in the absence of bile salt or lipoprotein, is able to initiate the mechanism that represses hepatic 3-hydroxy-3-methylglutaryl coenzyme A reductase.

1667 EFFECTS OF PHENOBARBITAL AND 3-METHYLCHOLANTHRENE ADMINISTRATION ON GLUTATHIONE-S-EPOXIDE TRANSFERASE ACTIVITY IN RAT LIVER. (Eng.) Mukhtar, H.; Bresnick, E. (Medical Coll. Georgia, Augusta, GA 30902). *Biochem. Pharmacol.* 25(9):1081-1084; 1976.

The effect of phenobarbital and 3-methylcholanthrene on glutathione-*S*-epoxide transferase activity in Sprague-Dawley rat liver was studied using three epoxide substrates. The specific activities in the high-speed liver supernatant fraction for 3-methylcholanthrene 11,12 oxide, styrene oxide, and 3,3,3-trichloro-1,2 epoxy propane were 5.7, 86.4, and 165 nmol/5 min/mg protein, resp. Phenobarbital (75 mg/kg, i.p., for 3 days) or 3-methylcholanthrene (20 mg/kg for 2 days) pretreatment resulted in a 40-60% increase in enzyme activity. β-Naphthoflavone (100 mg/kg, 2 days) had no effect on glutathione-*S*-epoxide transferase activity. The results indicate that the conjugation of the polycyclic hydrocarbon oxides with glutathione is elevated in the rat liver by pretreatment with phenobarbital or methylcholanthrene.

1668 ENHANCEMENT BY PHENOBARBITAL OF SOME EFFECTS OF CARBON TETRACHLORIDE ON MOUSE LIVER. (Eng.) Gans, J. H.; Korson, R.; Herman, J. (Coll. Medicine, Univ. Vermont, Burlington, VT 05401). *Biochem. Pharmacol.* 25(5):557-561; 1976.

The interaction of chronic CCl_4 and phenobarbital administration was studied in mice. Corn oil or a corn-oil CCl_4 mixture was administered p.o. twice a week for 7 or 8 weeks to male Swiss mice, which were maintained without or with phenobarbital sodium (30 mg/100 ml) in the drinking water. There was a significant increase in liver weight in CCl_4-treated mice maintained without phenobarbital Na in the drinking water and killed 48 hr after the last treatment. Histologically, livers from these CCl_4-treated mice were composed of areas of necrosis within lobules of regenerating hepatocytes, but deposition of collagen was scant. Synthesis of DNA, protein, and fatty acids *in vitro* was increased in liver tissue from CCl_4-treated mice. Combined treat ment with phenobarbital and CCl_4 produced additional significant increases in liver weight, but collagen deposition was slight. In liver tissue from mice treated with both phenobarbital and CCl_4, synthesis of DNA *in vitro* was significantly increased, protein synthesis was modestly increased, and fatty acid synthesis was unchanged when compared with liver tissue from CCl_4-treated mice, which were not given the barbiturate. Thus, phenobarbital did not accelerate or promote cirrhosis in livers of CCl_4-treated mice but it did enhance the effects of chronic CCl_4 treatment on liver weight, liver DNA synthesis, and, to a lesser extent, on liver protein synthesis.

1669 THE PARTICIPATION OF 2-BUTANONE IN 2-BUTANOL-INDUCED POTENTIATION OF CARBON TETRACHLORIDE HEPATOTOXICITY. (Eng.) Traiger, G. J.; Bruckner, J. V. (Sch. Pharmacy, Univ. Kansas, Lawrence, KS 66045). *J. Pharmacol. Exp. Ther.* 196 (2):493-500; 1976.

The role of alcohol metabolism in 2-butanol-induced potentiation of carbon tetrachloride (CCl_4) hepatotoxicity was studied in male Sprague-Dawley rats. Animals were sacrificed at various times after the administration of 2-butanol (2.2 ml/kg, p.o.) to determine blood 2-butanol and 2-butanone concentrations by gas chromatographic analysis. 2-Butanol exhibited an apparent elimination half-life of 2.5 hr. With the decline of 2-butanol concentrations, there was a rise in 2-butanone blood concentrations, with 43 mg/100 ml detected at 1 hr and a maximum of 105 mg/100 ml detected 4 hr following the administration of the alcohol. A 16-hr pretreatment with either 2-butanol (2.2 ml/kg, p.o.) or 2-butanone (1.87 ml/kg, p.o.) markedly enhanced the hepatotoxic response of CCl_4 (0.1 ml/kg, i.p.), as measured by serum glutamic pyruvic transaminase activity, hepatic glucose-6-phosphatase activity, and triglyceride content. The enhanced hepatotoxicity produced by 2-butanol was not significantly different from that produced by 2-butanone. The potentiation of CCl_4 hepatotoxicity by both agents was substantiated morphologically. The results suggest that 2-butanone production via the oxidation of 2-butanol appears to contribute to the marked response of 2-butanol.

1670 THE ROLE OF SERUM ALBUMIN IN THE HEPATIC EXCRETION OF IODIPAMIDE. (Eng.) Song, C. S.; Beranbaum, E. R.; Rothschild, M. A. (New York Univ. Sch. Medicine, New York, NY 10010). *Invest. Radiol.* 11(1):39-44; 1976.

The role of serum albumin on hepatic uptake and excretion of iodipamide was investigated in the isolated perfused rabbit liver. With the perfusate containing fully reconstituted rabbit plasma protein or 3.5 g/100 ml rabbit albumin alone, the iodipamide excretion was initially extremely slow. It then increased gradually to about 6 μg/g liver/min for 60 min; thereafter it remained constant. The half-time of transfer to the bile was about 130 min. Without albumin in the perfusate, the initial clearance rate of iodipamide was rapid, with half-time transfer to the bile of about 40 min. Rabbit serum globulins had no effect on iodipamide excretion. Thus, binding of iodipamide to albumin retards the transfer of iodipamide from plasma to the bile. This is probably due to competition between albumin and the anion binding protein of the liver.

1671 THE INFLUENCE OF DYE INFUSION RATE AND HEPATIC PLASMA FLOW ON INDOCYANINE GREEN CLEARANCE. (Eng.) Krarup, N.; Larsen, J. A. (Inst. Physiology, Univ. Aarhus, Universitetsparken, DK-8000 Aarhus C, Denmark). *Scand. J. Clin. Lab. Invest.* 36(2):183-188; 1976.

The hepatic clearance and extraction ratio of indocyanine green (ICG) were examined in 22 anesthetized cats when the infusion rate of the dye was increased stepwise and when the hepatic plasma flow was altered by replacing blood (15 ml/kg) with equal volumes of RBC, plasma, or dextran. Blood replacement with dextran increased the ICG elimination. Both plasma clearance and extraction ratio were independent of ICG infusion rate but they were dependent upon hepatic plasma flow. In contrast, a clearance calculated from the dye elimination rate and the estimated average hepatic plasma concentration of ICG was independent of changes in hepatic plasma flow. It is concluded that the plasma clearance and extraction ratio of indocyanine green are not ideal for estimating liver function. However, when clearance is calculated from the average hepatic plasma concentration of the dye, it becomes independent of hepatic plasma flow and is thus a more reliable index of liver function.

1672 THE PORPHYRINOGENIC EFFECTS OF KRYPTOPYRROLE IN THE RAT AND THE OCCURRENCE OF URINARY KRYPTOPYRROLE IN HUMAN HEREDITARY HEPATIC PORPHYRIA. (Eng.) Brodie, M. J.; Graham, D. J. M.; Thompson, G. G.; Moore, M. R.; Goldberg, A. (Stobhill General Hosp., Glasgow G21 3UW, Scotland). *Clin. Sci. Mol. Med.* 50(5):431-434; 1976.

The effect of kryptopyrrole on porphyrin synthesis was studied in 24 Sprague-Dawley rats. In addition, urinary kryptopyrrole excretion was studied in 17 patients with acute intermittent porphyria, hereditary coproporphyria, or variegate porphyria. Daily injections of 160 μmol of kryptopyrrole for 4 days increased urinary excretion of coproporphyrin and uroporphyrin in rats. Treatment with 0.119 μmol of δ-aminolevulinic acid (ALA) increased urinary excretion of coproporphyrin, uroporphyrin, ALA, and porphobilinogen. In animals treated with combined ALA and kryptopyrrole, the increase in porphyrin excretion was greater than the combined increases when ALA and kryptopyrrole were given separately. Kryptopyrrole was present in the urine of all patients with hereditary hepatic porphyria, in attack and in remission, but not in those with latent porphyria or in 10 normal subjects. The absence of

LIBRARY U. OF I.

kryptopyrrole in patients with latent porphyria suggests that it may be associated with changes, which transform latency to activity.

1673 RECIRCULATION AND REUTILIZATION OF MICELLAR BILE LECITHIN.

(Eng.) Robins, S. J. (VA Hosp., Boston, MA 02130). *Am. J. Physiol.* 229(3):598-602; 1975.

Bile lecithins solubilized in micellar bile salt and radiolabeled in the 1-acyl fatty acid, phosphorus, and choline positions, were infused in the small bowel of fasted Sprague-Dawley rats. Absorption of each label was virtually complete after 24 hr. However, these lecithins were extensively hydrolyzed in the bowel lumen as well as after absorption, and neither the fatty acid nor phosphorus was significantly retained in the enterohepatic circulation nor were they reutilized for biliary lecithin synthesis. While choline was also dissociated from absorbed lecithin, it was retained in the liver, reincorporated into newly synthesized hepatic lecithin, and secreted in biliary lecithin in 10-fold greater amounts than either the fatty acid or phosphorus. However, the extent of choline incorporation into bile lecithin was limited and was not further increased when free choline was directly injected into the portal vein. These data suggest that although only choline of absorbed lecithin is retained in the enterohepatic circulation and preserved for new biliary lecithin synthesis, exogenous choline utilization is regulated by the size of the available hepatic pool.

1674 LIGANDIN REVERSES BILIRUBIN INHIBITION OF LIVER MITOCHONDRIAL RESPIRATION IN VITRO.

(Eng.) Kamisaka, K.; Gatmaitan, Z.; Moore, C. L., Arias, I. M. (Albert Einstein Coll. Medicine, Bronx, NY). *Pediatr. Res.* 9(12):903-905; 1975.

The protective effect of ligandin on bilirubin-induced inhibition of mitochondrial respiration and phosphorylation was studied in Sprague-Dawley rats. Ligandin prevented the inhibitory effect of bilirubin on respiration and oxidative phosphorylation by isolated rat liver mitochondria. At equimolar concentrations of bilirubin and ligandin or human serum albumin, mitochondrial respiration was fully restored to control values. At greater ratios of bilirubin and ligandin or human serum albumin, the latter had a stronger protective effect. These studies suggest that ligandin may have a physiologic role in protecting mitochondrial systems against bilirubin toxicity.

1675 MODIFICATION OF PARACETAMOL TOXICITY BY ANTIOXIDANTS.

(Eng.) Kelleher, J.; Walker, B. E.; Keaney, N. P.; Losowsky, M. S.; Dixon, M. F. (St. James's Hosp., Leeds LS9 7TF, U.K.). *Biochem. Soc. Trans.* 4(2):292-294; 1976.

The effects of antioxidants against paracetamol hepatotoxicity were studied in Wistar rats. Groups of eight animals were pretreated with *NN*′-diphenyl-*p*-phenylenediamine (600 mg/kg), propylgallate (300 mg/kg), or tragacanth (control) at 72, 48, 24, and 6 hr before p.o. administration of paracetamol. At 48 hr, mortality in the control group was 0 of 24 as compared with 10 of 24 in animals treated with 12.8 or 19.2 nmol/kg paracetamol ($p<0.001$). At 6.4 nmol/kg paracetamol (at which dose all animal survived), the control group had only one animal wit high plasma aspartate aminotransferase activity at 24 hr, whereas four of eight in the group treated wi *NN*′-diphenyl-*p*-phenylenediamine had high enzyme leve For each experiment, the propylgallate-pretreated animals had a significantly lower mean enzyme activity, and none of these rats died, compared wit 3 of 16 control animals, after treatment with 19.2 nmol/kg of paracetamol. The fact that *NN*′-diphenyl-*p*-phenylenediamine enhanced rather than diminished hepatotoxicity suggests that the paracetamol toxicity is not mediated via a mechanism involvi lipid peroxidation.

1676 EFFECT OF POLYCHLORINATED BIPHENYLS (PCBs) ADMINISTRATION ON PHOSPHOLIPID BIOSYNTHESI IN RAT LIVER.

(Eng.) Ishidate, K.; Nakazawa, Y. (Tokyo Medical and Dental Univ., Tokyo, Japan). *Biochem. Pharmacol.* 25(11):1255-1260; 1976.

The effect of polychlorinated biphenyls (PCB's) or phenobarbital on the biosynthesis of phospholipids in hepatic endoplasmic reticulum of Wistar rats was studied by the i.p. injection of (^{32}P)orthophosphate (Me-^{14}C)choline or (2-^{3}H)glycerol. Significant increases in liver microsomal phospholipid content after the administration by gastric intubation of either PCB's (100 mg/kg/day) or phenobarbital (80 mg kg/day) indicated the actual proliferation of endoplasmic reticulum membranes. The rate of both (^{32}P) and (^{14}C) incorporations into microsomal choline-containing phospholipids, such as phosphatidylcholine, sphingomyelin and lysophosphatidylcholine, was reduced to one-fifth by PCB's administration, compared with control animals. The incorporation of (^{32}P)orthophosphate into phosphatidylethanolamine or other phospholipid classes was less or not affected, resp., by PCB's administration. The specifi inhibitory effect of PCB's on the incorporation into choline-containing phospholipids was not observed when (2-^{3}H)glycerol was used as a precursor. However, phenobarbital administration significantly increased the rate of (^{32}P)incorporation into liver phospholipids, especially phosphatidylcholine. It is suggested that the increase in microsomal phospholipid content by PCB's administration is not due to the stimulation of synthesis but is due to the inhibition of the catabolism of membrane phospholipids In addition, the increase in content caused by phenobarbital is due, at least in part, to the stimulatio of synthesis.

1677 INJURIOUS EFFECT ON RAT LIVER MITOCHONDRIA BY LYMPHOCYTES FROM PATIENTS WITH PRIMARY BILIARY CIRRHOSIS.

(Eng.) Bootello, A.; Fernandez-Cruz, E.; Escartin, P.; Blanco, M. F.; Gosalvez, M.;

Segovia de Arana, J. M. (Clinical Puerta de Hierro, San Martin de Porres 4, Madrid 35, Spain). *Clin. Exp. Immunol.* 21(2):374-377; 1976.

The effects of lymphocytes of patients with primary biliary cirrhosis (PBC) on the function of rat liver mitochondria were investigated. Lymphocytes of patients with PBC, as well as those of healthy controls and of patients with other liver diseases were incubated for 20 min with isolated rat liver mitochondria (5-20 x 10^6 cells/mg mitochondrial protein), and the respiratory control (i.e., the ratio between respiration with ADP and respiration without ADP) was determined. In the absence of lymphocytes, mitochondria had an average respiratory control of 8.4, which was considered to be 100%. Mitochondria incubated with lymphocytes of nine normal subjects, of five patients with alcoholic cirrhosis, and of four patients with miscellaneous liver diseases had 80-84% respiratory control, whereas mitochondria incubated with the lymphocytes of seven patients with PBC had 11% respiratory control. The results suggest that the injurious effect of PBC lymphocytes on mitochondria may be a consequence of *in vivo* sensitization of the PBC patients' lymphocytes by the mitochondrial antigen(s).

1678 ABNORMAL LOW DENSITY PLASMA LIPOPROTEINS OCCURRING IN DOGS WITH OBSTRUCTIVE JAUNDICE. (Eng.) Danielsson, B.; Ekman, R.; Johansson, B. G.; Petersson, B. G. (Inst. Biochemistry, Univ. Lund, Lund, Sweden). *FEBS Lett.* 63(1):33-36; 1976.

The plasma lipoprotein distribution was studied in six dogs, by zonal ultracentrifugation, after surgical induction of obstructive jaundice to study the abnormal lipoprotein metabolism in liver-biliary disease. In these and in two sham-operated dogs, two classes of low density plasma lipoproteins that reacted with anti-β-lipoprotein were resolved (LDL_1 and LDL_2). The LDL from the dogs with obstructive jaundice were markedly increased, and an additional LDL_1 fraction without immunoreactivity against anti-β-lipoprotein was found in their plasma. This fraction (designated cholestatic lipoprotein, CLP) resembled the human lipoprotein X in the following respects: both were lipoproteins in the LDL class, occurring in cholestasis with cathodic migration in agar gel electrophoresis; both had high contents of phospholipids and low contents of triglycerides; and both lacked B-protein. The CLP in the dogs, however, differed from the X lipoprotein in the cholesterol ester/cholesterol ratio and apoprotein composition. These differences suggest that obstructive jaundice does not affect the metabolism of cholesterol in the dog in the same way that it does in man.

1679 MODIFICATION OF THE HEPATOTOXICITY OF D-GALACTOSAMINE IN THE RAT BY CYCLOHEXIMIDE. (Eng.) Koff, R. S.; Connelly, L. J. D. (Boston Veterans Admin. Hosp., Boston, MA 02130). *Proc. Soc. Exp. Biol. Med.* 151(3):519-522; 1976.

The effect of cycloheximide on D-galactosamine-induced hepatic necrosis and on hepatic triglyceride accumulation was studied in female CD rats. Twenty-four hr after D-galactosamine (i.p. administration, 375 mg/kg), serum transaminase levels were significantly reduced in animals treated with cycloheximide (1.5 mg/kg) at the same time as, or 4 hr before, D-galactosamine administration. Transaminase levels in rats given cycloheximide 4 hr after D-galactosamine were not reduced. Histological grading of hepatocyte necrosis showed a similar pattern of protection in the pretreated and simultaneously treated groups. Hepatic triglycerides were significantly reduced only in the latter group. Fatality 48 hr after D-galactosamine administration was significantly less common in rats pretreated with cycloheximide (2/14) when compared to rats given D-galactosamine without cycloheximide (9/13), and surviving animals in the cycloheximide-pretreated group had a lower serum transaminase level, a lower necrosis score, and a reduced hepatic triglyceride level. These data support the concept that protein synthesis is important in the pathogenesis of D-galactosamine-induced hepatotoxicity.

1680 ALTERATIONS OF LIVER AND SPLEEN FOLLOWING INTRAVENOUS INFUSION OF FLUOROCARBON EMULSIONS. (Eng.) Rosenblum, W. I.; Hadfield, G.; Martinez, A. J.; Schatzki, P. (Division Neuropathology, Box 17, Medical Coll. Virginia Station, Richmond, VA 23298). *Arch. Pathol. Lab. Med.* 100(4):213-217; 1976.

Swiss mice were injected via tail vein with emulsions of fluorocarbon (FC; 0.5, 1.0, or 1.5 ml), a potential blood substitute. Different types of FC's were used: FC-47 ($C_{12}F_{27}N$), P11D ($C_{14}F_{30}O_2$), E_4 ($C_{14}HF_{29}O_4$), PP-5 ($C_{10}F_{18}$), and PP-9 ($C_{11}F_{20}$). All produced vacuolar changes in hepatocytes, and in reticuloendothelial cells throughout the body. In the liver, occasional inflammatory foci were also observed, but fibrosis was never seen. The vacuolated cells, presumably containing FC, were found as late as 1 yr following a single infusion. However, such cells might also disappear from the liver and spleen. The numbers of affected cells and their rate of disappearance depended on the type of FC, the amount of FC infused, and the length of time between infusion and killing. Fluorodecalins, especially PP-5, produced the least amount of change and the most readily reversible change of all FCs tested. These observations suggest that PP-5 would be more suitable as a blood substitute than the other FC's tested. However, other studies have shown that apparently healthy long-term survival is obtainable even when the infused FC is one that produces extreme vacuolar change in the liver and spleen.

SECRETION AND METABOLISM

Intestine

1710 ORGAN CULTURE OF HUMAN DUODENUM AND JEJUNUM. (Eng.) Hauri, H.-P.; Kedinger, M.; Haffen, K.; Grenier, J.-F.; Hadorn, B. (Universitats-Kinderklinik, Freiburgstrasse 23, CH-3010 Berne, Switzerland). *Biol. Gastroenterol. (Paris)* 8(4):307-319; 1975.

The protein synthesizing ability of human duodenum and jejunum, the effect of different culture media on brush border enzyme activity, and enzyme release into the culture medium were investigated as a function of time. Human duodenal and jejunal mucosal specimens obtained from operations were cultured for 48 hr in Trowell T8 medium. Ultrastructural and ultracytochemical studies revealed a good preservation of the tissue even after 48 hr.

LIBRARY U. OF I.

Protein synthesis, measured by the incorporation of labeled leucine, continued at a constant rate throughout the culture period. When Trowell T8 medium was used, alkaline phosphatase showed an increase up to 24 hr, followed by a decrease to the level of noncultured explants. When RPMI 1640 medium (supplemented with glucose, insulin, and glutamine) was used, alkaline phosphatase showed a sustained increase up to 48 hr. Regardless of the type of medium used, sucrase activity remained constant up to 24 hr and decreased thereafter to a lower level. Total enzyme activity (explant plus medium) showed a 170% increase for alkaline phosphatase and an increase of 320% for aminopeptidase after 48 hr. About 50% of the enzyme activity determined in the medium was bound to particles. The results demonstrate a steady time-dependent increase of total but an unchanged ratio of soluble to nonsoluble enzyme activities in the medium for aminopeptidase and alkaline phosphatase in organ culture, suggesting that a large amount of enzymatic activity is released continuously be cell extrusion.

1711 ENZYMIC SOLUBILIZATION OF THE HUMAN INTESTINAL BRUSH BORDER MEMBRANE ENZYMES.

(Eng.) Maestracci, D. (Faculty Medicine, Universite de Montreal, C.P. 6208, Succursale A, Montreal H3C 3T8, Canada). *Biochim. Biophys. Acta* 433(3):469-481; 1976.

The release of proteins, maltase, lactase, sucrase, trehalase, alkaline phosphatase, γ-glutamyltransferase, and leucylnaphthylamide-hyrolyzing activity from human intestinal brush border membrane vesicles by various enzymes (especially pancreatic proteases) were studied. Full-thickness sections of macroscopically normal small intestine were obtained from 16 patients and were analyzed by electron microscopy, gel electrophoresis, and enzyme assays. The brush border membrane enzymes were not solubilized by digestion with trypsin and chymotrypsin, but they were released after treatment with papain (10 μg/ml) or elastase (18 U/ml). Most of the enzymes were fully active after the proteolytic treatment. All proteins released by papain and elastase were identified by electrophoresis as already known intestinal hydrolases. Electron microscopy of brush border membrane vesicles demonstrated "knob-like" structures (particles) attached to the external side of the membrane. During papain treatment, enzyme removal paralleled the disappearance of the particles. During elastase treatment, it was not possible to correlate the release of the enzymic activities with the removal of the particles. The results indicate that most of the intestinal hydrolases are surface components attached to the external side of the membrane. This supports the concept that the brush border membrane enzymes are organized within the membrane in a mosaic-like pattern.

1712 METABOLISM OF CHENODEOXYCHOLATE BY INTESTINAL MUCOSA.

(Eng.) Rachmilewitz, D.; Saunders, D. R. (Univ. Washington, Sch. Medicine, Seattle, WA). *Gastroenterology* 71(1):82-86; 1976.

The metabolism of ^{14}C-labeled bile salts was studied *in vitro* during their absorption from infused segments of rat and human intestine. The transported bile salts were recovered in transudates, which were collected from the serosal surface of infused segments. In the jejunum, 36% of transported [^{14}C]-deoxycholate and 48% of transported [^{14}C]chenodeoxycholate were recovered as metabolites, which migrated as a seemingly single polar compound, on thin layer chromatography; 52%-72% of these metabolites were deconjugated by cholylglycine hydrolase to yield original [^{14}C]deoxycholate or [^{14}C]chenodeoxycholate resp. The jejunum metabolized 9 times more [^{14}C]-chenodeoxycholate than the ileum (38.1 nmoles/hr/g compared with 4.2 nmoles/hr/g), despite the fact that both segments transferred the same amount of radioactivity. In contrast, [^{14}C]cholate, [^{14}C]-glycocholate, and [^{14}C]glycodeoxycholate were transferred intact by the jejunum, ileum, and colon. Human jejunal and rectal mucosa were able to metabolize [^{14}C]chenodeoxycholate to polar metabolites *in vitro*. Polar metabolites were also found in the portal plasma and jejunal wall 20 min after the intraduodenal injection of [^{14}C]chenodeoxycholate to bile fistula rats. It is suggested that these results complicate the interpretation of *in vitro* experiments on absorption of dihydroxy bile salts, and that they indicate that the human small intestine may be able to metabolize chenodeoxycholate.

1713 RELATIONSHIP BETWEEN THE CHANGES IN GASTRIN LEVELS AND INTESTINAL PROPERTIES IN THE STARVED RAT.

(Eng.) Lichtenberger, L.; Welsh, J. D.; Johnson, L. R. (Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA 02115). *Am. J. Dig. Dis.* 21(1):33-38; 1976.

The decrease in intestinal mucosal DNA, RNA, and protein is greater than the loss of body weight in the starved rat; these disproportionate changes were investigated to determine whether they are caused by the low levels of gastrin during starvation. Male King-Holtzman rats (45-day-old) were fasted for 0, 1, 2, 3, or 5 days. Specific lactase and maltase activity increased with progressively longer periods of starvation. Antral and serum gastrin concentration significantly decreased during the 3 days of starvation. Pentagastrin (250 μg/kg, 3 times daily), injected s.c. into a group of rats for the duration of a 3-day starvation period, caused a small but significant increase in the relative intestinal RNA and protein content. Lactase and maltase specific activities were also decreased in comparison with the levels of 3-day starved controls. Pentagastrin partially reversed some the starvation-induced changes, approaching fed levels. Thus, a deficiency in gastrin may be partially responsible for the disproportionate changes in intestinal tissue during starvation.

1714 RELEASE OF MOTILIN AFTER DUODENAL ACIDIFICATION.

(Eng.) Mitznegg, P.; Bloom, S. R.; Domschke, W.; Domschke, S.; Wunsch, E.; Demling, L. (Dept. Pharmacology, Univ. Erlangen-Nurnberg, D-852 Erlangen Universitatsstr. 22, Munich, W. Germany). *Lancet* 1(7965):888-889; 1976.

The effect of intraduodenal infusion of alkaline and acidic solutions was investigated in six male volunteers to determine an agent that would stimulate motilin release in man. The subjects received 3-min infusions of 50 ml 0.3 mol/l "tris" buffer (pH 10.3), 0.1 mol/l HCl, or 0.9% NaCl. After acid infusion, plasma-motilin rose by 90% at 4 min and was still significantly raised at 45 min. There was an insignificant fall in plasma-motilin after alkali and no change after saline. Results indicate that release of motilin after duodenal acidification may be an important factor in inhibiting gastric emptying.

1715 ORGANIC ANIONS INDUCE COLONIC SECRETION.

(Eng.) Bustos-Fernandez, L.; Gonzalez, E.; De Paolo, I. L.; Celener, D.; De Furuya, K. O. (Instituto de Gastroenterologia, Potosi 4215, Buenos Aires, Argentina). *Am. J. Dig. Dis.* 21(4):329-332; 1976.

Colonic function was studied after the instillation of solutions containing acetate or acetic acid, at different pH levels, into the cleansed colons of anesthetized Wistar rats. Isotonic test solutions at an acid (2.9) or neutral (7.0) pH were used. At the lower pH, acetic acid was absorbed and water was secreted. At the higher pH, acetate ions were less well absorbed, and the colon absorbed fluid. The secretory effect could not be reproduced by HCl solutions at pH 2.9. Fluid secretion induced by acetic acid was associated with mucous discharge from goblet cells. The interference of colonic absorption by acetic acid may have importance in some diarrheal diseases.

1716 INHIBITION BY PROPRANOLOL OF BILE ACID STIMULATION OF RABBIT COLONIC ADENYLATE CYCLASE IN VITRO.

(Eng.) Coyne, M. J.; Bonorris, G. G.; Chung, A.; Conley, D. R.; Croke, J.; Schoenfield, L. J. (Cedars-Sinai Medical Center, Los Angeles, CA 90048). *Gastroenterology* 71(1):68-71; 1976.

The *in vitro* effect of bile acids (deoxycholic acid and taurocholic acid), NaF, catecholamines (epinephrine and norepinephrine), and propranolol on adenylate cyclase (AC) activity was determined in rabbit colonic mucosa. NaF (10^{-4} M) increased AC activity to 220% of control ($p<0.01$). Deoxycholic acid (10^{-4} M) increased AC activity to 178% of control ($p<0.01$). Lesser but significant ($p<0.01$) stimulation of AC occurred at both higher and lower concentrations of deoxycholic acid, with no effect at 10^{-10} M. Taurocholic acid (10^{-4} M) and epinephrine and norepinephrine (10^{-2} M, 10^{-4} M, 10^{-6} M, and 10^{-8} M) had no effect on AC. Propranolol (10^{-6} M) caused a 60% decrease ($p<0.01$) in the stimulated AC activity induced by 10^{-4} M deoxycholic acid. Propranolol (10^{-4} M) decreased basal AC by 30% ($p<0.01$). The results indicate that: deoxycholic acid, but not taurocholic acid, epinephrine, or norepinephrine, stimulates colonic AC activity; propranolol inhibits this deoxycholic acid stimulation of AC; and catecholamines are not intermediaries in this action of propranolol on colonic mucosal AC activity.

1717 PROPRANOLOL INHIBITS ADENYLATE CYCLASE AND SECRETION STIMULATED BY DEOXYCHOLIC ACID IN THE RABBIT COLON.

(Eng.) Conley, D.; Coyne, M.; Chung, A.; Bonorris, G.; Schoenfield, L. (Cedars-Sinai Medical Center, Los Angeles, CA 90048). *Gastroenterology* 71(1):72-75; 1976.

The effects of the adenylate cyclase inhibitor, propranolol, on deoxycholic acid (DCA) stimulation of net secretion and on the cyclic AMP system were determined in the colon. In each of 30 New Zealand white rabbits, 6 mM and 8 mM DCA were injected in random sequence into three colonic loops *in situ*. Propranolol (4 mg/kg) was administered i.v. to 12 of the 30 rabbits 1/2 hr before preparation of the loops, i.e., 5 1/2 hr before the rabbits were killed. In the 18 untreated animals, 6 and 8 mM DCA significantly stimulated colonic net secretion and mucosal adenylate cyclase activity; 6 mM DCA caused no change in mucosal phosphodiesterase activity, whereas 8 mM DCA caused a 25% decrease ($p<0.01$). In propranolol-treated animals compared to untreated animals, the volume of luminal fluid in controls was not different; with 6 mM DCA it was 88% less ($p<0.01$), and with 8 mM DCA it was 45% less ($p<0.01$); adenylate cyclase activity in controls was 43% less ($p<0.01$), with 6 mM DCA it was 67% less ($p<0.01$), and with 8 mM DCA it was 65% less ($p<0.01$); phosphodiesterase activity in controls and with 6 mM DCA was not different, and with 8 mM DCA, it was 38% greater ($p<0.02$). It is concluded that propranolol prevents DCA stimulation of colonic net secretion, and it inhibits the cyclic AMP system. Propranolol, therefore, warrants investigation as therapy for diarrhea caused by bile acids in the colon.

1718 INHIBITION OF ENTEROTOXIN-INDUCED INTESTINAL SECRETION BY THE POLYPEPTIDE ANTIBIOTIC, POLYMYXIN.

(Eng.) Maimon, H. N.; Mitch, W. E.; Banwell, J. G.; Hendrix, T. R. (Johns Hopkins Univ. Sch. Medicine, Baltimore, MD). *Johns Hopkins Med. J.* 138(3):82-90; 1976.

The effects of polymyxin on the interaction between cholera enterotoxin (CT) and intestinal mucosa, and its inhibitory influence on intestinal fluid secretion, caused by *Escherichia coli* enterotoxin, were studied. Rabbit jejunal loops were exposed to 1 mM polymyxin sulfate for 30 min prior to CT exposure and recirculatory perfusion with an isotonic electrolyte solution for 6 hr. After 3 hr, net fluid secretion into the lumen was decreased 96% by polymyxin pretreatment, compared to loops exposed to cholera toxin alone. Net fluid secretion in polymyxin pretreated, CT exposed loops gradually developed, although 78% inhibition could be maintained throughout the 6-hr study when polymyxin was included in the electrolyte perfusate. Progressive loss of ^{3}H-polymyxin occurred from villi and crypt fractions and its concentration increased in the perfusate, indicating that secretion resumed when polymyxin concentration at the mucosal surface declined. Polymyxin inhibition of CT secretion was not observed unless mucosa was pre-exposed to the antibiotic. Polymyxin inhibited the intestinal secretory response to *E. coli* enterotoxin, as well as CT; ganglioside, a phospholipid, which specifically deactivates CT, only inhibited CT-induced secretion.

1719 PREVENTION AND REVERSAL OF CHOLERA ENTEROTOXIN-INDUCED INTESTINAL SECRETION BY METHYLPREDNISOLONE INDUCTION OF Na^+-K^+-ATPase. (Eng.) Charney, A. N.; Donowitz, M. (Walter Reed Army Medical Center, Washington, DC 20012). *J. Clin. Invest.* 57(6):1590-1599; 1976.

The relation of the mucosal enzyme systems Na^+-K^+-activated adenosine triphosphatase (Na-K-ATPase) and adenylate cyclase and their associated intestinal transport processes was studied in the Walter Reed rat ileum. Two ileal loops were constructed in each anesthetized rat; one loop was inoculated with saline, the other loop with cholera enterotoxin dissolved in saline (choleragen). Net transport of water and electrolytes was measured *in vivo* and enzyme activity was measured in the mucosa of the perfused loops. All doses of choleragen between 5-150 μg decreased water movement as early as 3.5 hr after inoculation. A linear relationship between the dose of choleragen and the level of net water and electrolyte secretion was observed when choleragen doses between 5-150 μg were incubated in ileal loops for 4 hr. Adenylate cyclase activity was always increased in secreting intestinal loops, whereas Na-K-ATPase was unaffected by choleragen. In animals pretreated with methylprednisolone acetate (3 mg/100 g/day, s.c.) for 3 days before loop inoculation, saline loops enhanced mucosal Na-K-ATPase activity and increased net water and electrolyte absorption; choleragen-exposed loops increased adenylate cyclase and Na-K-ATPase activities and net absorption of water and electrolytes 4 hr after inoculation. These effects of methylprednisolone acetate were still present 19.5 hr after inoculation. When a single injection of methylprednisolone acetate was given 3.5 hr after choleragen inoculation, both adenylate cyclase and Na-K-ATPase were activated, and net intestinal absorption of water and electrolytes was observed 19.5 hr after inoculation. These results suggest that methylprednisolone can prevent and reverse the secretory effects of choleragen by selectively stimulating a coexisting absorptive process.

1720 PROSTAGLANDIN E_2: A FACTOR IN THE PATHOGENESIS OF CHOLERA. (Eng.) Tothill, A. (Middlesex Hosp. Medical Sch., Windeyer Building, Cleveland St., London W1P 7PN, England). *Prostaglandins* 11(6):925-934; 1976.

The role of prostaglandin E_2 in the pathogenesis of cholera was investigated. Injection of cholera toxin *in vivo* into loops of Sprague-Dawley rat intestine caused the production of an exudate. An assay on the rat stomach strip and thin-layer chromatography revealed the presence of prostaglandin E_2. The amounts ranged from 20-40 ng/loop of intestine. Introduction of 30 ng of prostaglandin E_2 into intestinal loops caused the production of an exudate similar in volume to that found after the introduction of cholera toxin. These results indicate that the exudate in cholera is caused by the action of prostaglandin liberated by the enterotoxin. It is suggested that an inhibitor of prostaglandin release be added to the solutions used in treatment for the restoration of fluids and electrolytes, to block the action of toxin still present in the intestinal lumen, thereby achieving a more rapid therapeutic result.

1721 ALCOHOL AND ABSORPTION FROM THE SMALL INTESTINE. 2. EFFECT OF ETHANOL ON ATP AND ATPase ACTIVITIES IN GUINEA-PIG JEJUNUM. (Eng.) Krasner, N.; Carmichael, H. A.; Russell, R. I.; Thompson, G. G.; Cochran, K. M. (Stobhill General Hosp., Glasgow, Scotland). *Gut* 17(4):249-251; 1976.

The effects of the acute and chronic administration of ethanol on ATP levels and adenosine triphosphatas (ATPase) activities were studied in the guinea pig jejunum. The exposure of isolated segments of jejunum to 2% ethanol, for 1 hr, caused a significan reduction ($p<0.001$) in the ATP content, when compared with levels found in segments perfused with Krebs' solution. However, no alteration was noted in the activity of ATPase. The chronic administration of 50% ethanol in a dose of 2·5 g/kg for 2 weeks did not affect either the ATP centent or ATPas activity in jejunal mucosa. It is suggested that intestinal dysfunction in alcoholics is probably a direct effect of recent ethanol ingestion.

1722 INFLUENCE OF CERTAIN INDIGENOUS GASTROINTESTINAL MICROORGANISMS ON DUODENAL ALKALINE PHOSPHATASE IN MICE. (Eng.) Yolton, D. P.; Savage, D. C. (2010 Laurel St., Forest Grove, OR 97116). *Appl. Environ. Microbiol.* 31(6):880-888; 1976.

Mechanisms by which indigenous microbiota influence alkaline phosphatase activity were investigated in duodenal homogenates or extracts from adult specific pathogen-free (SPF) and germfree mice and in gnotobiotic mice mono-associated with a *Lactobacillus* sp., a *Bacteroides* sp., or a coliform strain indigenous to SPF mice. Activity levels of the enzyme were much higher in the preparations from germfree mice than in those from the SPF controls. In the gnotobiotes mono-associated either with a freshl isolated *Lactobacillus* sp. or a *Bacteroides* sp., the levels of alkaline phosphatase activity were intermediate between the values for germfree and SPF mice. In the gnotobiotes mono-associated with a coliform strain, alkaline phosphatase activity remained at high germfree levels. Butanol extracts of duodenal tissue from SPF mice, germfree mice, and ex-germfree mice, associated with an indigenous microflora from SPF mice (conventionalized), were subjected to acrylamide gel electrophoresis. A stain for alkaline phosphatase activity revealed three major bands in the gels prepared with extracts from SPF and conventionalized mice, but only two in the gels prepared with extracts from germfree mice. All three bands may have been present in the latter gels. One of the bands (the middle one) may have been obscured, however, by high activity in the slowest moving band. As determined by densitometric scanning, the slowest moving band had much higher activity in the preparations from germfree animals than in those from SPF or conventionalized mice. These findings suggest that the indigenous microbial flora affects, both quantitatively, and qualitatively, the activity of alkaline phosphatases in the mouse intestinal mucosa.

1723 THE FUNCTIONAL RESPONSE OF THE DOG ILEUM TO ONE HOUR'S ISCHAEMIA.

(Eng.) Robinson, J. W. L.; Menge, H.; Sepulveda, F. V.; Cobo, F.; Mirkovitch, V. (Hopital Cantonal Universitaire, CH-1011 Lausanne, Switzerland). *Clin. Sci. Mol. Med.* 50(2):115-122; 1976.

The absorptive capacity of the ischemic intestine of the dog was studied simultaneously *in vivo* and *in vitro*; in addition, the regenerating epithelium was studied morphometrically and histochemically. A loop of ileum, approximately 40 cm above the cecum, was subjected to arterial ischemia for 1 hr, and the afferent artery and the intestinal wall at each end of the loop were clamped; the efferent vein was left open, and nothing was introduced into the lumen. The function and structure of the ileal mucosa were examined immediately after arterial ischemia and 1, 3, or 7 days after the trauma. Immediately after the ischemia, there was a net movement of water and ions into a luminal perfusate *in vivo*. One day later, there was no net movement of water and electrolytes, but net absorption returned on the third day. Active transport of phenylalanine or β-methylglucoside by mucosal strips *in vitro* was abolished immediately after the trauma, but it was largely restored 1 day later. There was a close correlation between glucose absorption *in vivo* and β-methylglucoside uptake *in vitro*. Morphological study revealed pronounced desquamation of enterocytes immediately after the trauma. The regenerating mucosa had shorter villi and crypts and lower enzyme activities, assessed histochemically 1 day later. Most parameters returned to normal by the third postoperative day.

1724 THE UTILIZATION OF GLUCOSE AND PRODUCTION OF LACTATE BY IN VITRO PREPARATIONS OF RAT SMALL INTESTINE: EFFECTS OF VASCULAR PERFUSION.

(Eng.) Hanson, P. J.; Parsons, D. S. (Dept. Biochemistry, Univ. Oxford, Oxford, England). *J. Physiol. (London)* 255(3):775-795; 1976.

The metabolism rate of glucose to lactate was measured in a number of nonvascularly perfused preparations of rat jejunum *in vitro*. The glucose and lactate metabolism were measured simultaneously and under conditions such that the uptake of glucose and the appearance of lactate were linearly related to time. There was no difference between the rates at which rings of rat jejunum utilized glucose during the first 45 min of anaerobic or aerobic incubation. During the first 15 min of incubation, 60-70% of the metabolized glucose was converted to lactate under aerobic conditions; this value increased to 80-90% during the subsequent 30 min. During this same period, lactate production was higher under anaerobic than under aerobic conditions, but after this initial period, the rate of lactate production was the same under both conditions. For segments of rat jejunum, maintained *in vitro* by the recirculation of nutrient fluid through the intestinal lumen, neither the rate of production of lactate, nor the utilization of glucose, was stimulated if the preparation was maintained under anaerobic conditions. The direct delivery of gas (in a stream of bubbles) into the intestinal lumen (segmented circulation) reduced both the utilization of glucose and the production of lactate under aerobic conditions. However, no effect on glucose metabolism was observed under anaerobic conditions. The finding of a Pasteur effect with the segmented-circulated preparation, but not with the simple recirculated preparation, is associated with the lower rate of aerobic lactate production in the former preparation It is suggested that under conditions of segmented circulation, the luminal compartment is better stirred, thereby increasing access of O_2 to the tissue.

1725 A STUDY OF THE 5-HYDROXYTRYPTAMINE DISTRIBUTION IN ENTEROCHROMAFFIN CELL GRANULES USING ANALYTICAL ELECTRON MICROSCOPY.

GENERAL

1742 THE SIZE, pH, AND REDOX POTENTIAL OF THE CECUM IN MICE ASSOCIATED WITH VARIOUS MICROBIAL FLORAS. (Eng.) Celesk, R. A.; Asano, T.; Wagner, M. (Dept. Microbiology, Univ. Notre Dame, Notre Dame, IN 46556). *Proc. Soc. Exp. Biol. Med.* 151(2):260-263; 1976.

Cecal size, cecal *in situ* redox potential (Eh), and pH of cecal contents were determined in CFW mice. The animals were treated either conventionally or under a variety of gnotobiotic conditions, including germfree, mono-associated with a cecal *Clostridium* species, hexaflora-associated, and thermoduric polyflora-associated. The mean Eh was approximately +200 mV in germfree mice and -200 mV in the conventional mice. The Eh was close to zero in the mono-associated mice, thus occupying an intermediate position between the germfree and conventional mice. The potentials observed in the hexaflora and the thermoduric flora groups were indistinguishable from those of conventional animals. The degree of normalization was more advanced with respect to the redox potential than to the cecal size in the various gnotobiotic groups. In the thermoduric polyflora-associated group, normalization was observed in both cecal size and redox potential. This demonstrates that normalization can be accomplished with a relatively simplified microflora.

1743 EVIDENCE FOR A COLON CHALONE. (Eng.)

Houck, J. C.; Kanagalingam, K.; Kaufman, S. L.; Sunshine, G. (Res. Foundation Children's Hosp., Washington, DC 20009). *J. Natl. Cancer Inst.* 56(5):899-902; 1976.

The concept that a specific and endogenous mitotic inhibitor controls cellular proliferation was tested *in vitro* in human colon carcinoma cells (SW-48). The molecular weight fractions of 10,000-50,000 daltons prepared from "used" medium (obtained during cultivation of SW-48 cells) inhibited the proliferation and DNA synthesis of these cells. Fractions exceeding 50,000 daltons were not inhibitory; those less than 10,000 daltons were cytotoxic. The inhibitory fraction did not affect either proliferation of human fibroblasts or transformation of human lymphocytes *in vitro*. Similar fractions from the colon mucosa of humans and other species inhibited the proliferation of SW-48 cells (humans, 95%; pigs, 83%; and dogs, 64% inhibition), whereas extracts of dog jejunum or lung did not. This mitotic inhibition was completely reversible and could be destroyed by preincubation with trypsin. Therefore, colon cells appear to contain a cell- (but not species-) specific, endogenous mitotic inhibitor or chalone.

1744 CYTOTOXIC EFFECTOR CELL FUNCTION IN ORGANIZED GUT-ASSOCIATED LYMPHOID TISSUE (GALT). (Eng.)

Nelson, D. L.; Bundy, B. M.; Blaese, R. M.; Strober, W. (Building 10, Room 4N114, Natl. Inst. Health, Bethesda, MD 20014). *Cell. Immunol.* 22(1):165-175; 1976.

Lymphocytes from the organized gut-associated lymphoid tissues (GALT) of adult guinea pigs were examined for surface markers characteristic of thymus-derived (T) and bone-marrow-derived (B) lymphocytes. In addition, their capacity to function as effector cells in mitogen-induced cellular cytotoxicity (MICC) and antibody-dependent cellular cytotoxicity (ADCC) reactions was investigated. GALT lymphocytes formed rosettes with rabbit RBC, a T-cell marker, and underwent proliferative responses *in vitro* in the presence of phytohemagglutinin (PHA), concanavalin A (Con A), and pokeweed mitogen (PWM). GALT lymphocytes were cytotoxic *in vitro* for RBC and DBA mastocytoma targets in the presence of PHA. A population of GALT lymphocytes bound aggregated γ-globulin; however, they functioned poorly in ADCC reactions. Thus, organized GALT in the guinea pig contains lymphocytes capable of functioning in T-cell-dependent MICC reactions but either lacks the effector cell population that mediates ADCC or contains an effector cell that functions poorly in ADCC.

1745 GIARDIASIS IN THE MOUSE: AN ANIMAL MODEL.

(Eng.) Roberts-Thomson, I. C.; Stevens, D. P.; Mahmoud, A. A. F.; Warren, K. S. (Case Western Reserve Hosp., Cleveland, OH 44106). *Gastroenterology* 71(1):57-61; 1976.

An animal model for giardiasis was developed using *Giardia muris* in female Swiss albino mice. Intraesophageal inoculation of *G. muris* cysts caused a reproducible pattern of infection, with trophozoite and cyst counts reaching a maximum on days 5 to 14 after cyst inoculation and thereafter showing a progressive decline. Spontaneous resolution of infection occurred in most mice after 21-28 days. When compared to uninfected controls, Giardia-infected mice had significant impairment of weight gain and a significant reduction in the villus to crypt ratio of jejunal mucosa. Although maximal trophozoite and cyst counts were independent of the size of the cyst inoculum, those mice receiving inoculations of larger numbers of cysts (1,000 or 10,000) showed earlier attainment of maximal counts, greater impairment of weight gain, and earlier and more severe small bowel changes than mice receiving inoculations of smaller numbers of cysts (100). This model offers opportunities for study of this poorly understood gastrointestinal parasite.

1746 AN ANIMAL MODEL OF FULMINANT HEPATIC FAILURE: A FEASIBILITY STUDY. (Eng.)

Miller, D. J.; Hickman, R.; Fratter, R.; Terblanche, J.; Saunders, S. J. (Dept. Medicine, Univ. Cape Town, Cape Town, South Africa). *Gastroenterology* 71(1):109-113; 1976.

An attempt was made to produce an animal model of fulminant hepatic failure in the pig by intragastric administration of acetaminophen (*N*-acetyl-*p*-aminophenol). The effect of varying doses (1.0-4 g/kg) was observed in phenobarbital-pretreated (45 mg/kg, i.m. for 3 days) and in untreated animals. Assessment of optimal dose was made in terms of duration of survival and coma in animals exhibiting biochemical and histological evidence of liver necrosis. Significant liver necrosis was observed in enzyme-induced pigs only, whereas in the noninduced pigs,

LIBRARY U. OF I.

respiratory arrest was considered a likely cause of death. Although liver necrosis occurred consistently at a dose of 0.5 to 1.1 g/kg of acetaminophen in phenobarbital-pretreated animals, survival time and coma duration were unpredictable. Only 20% of the total number of phenobarbital-pretreated pigs administered acetaminophen in this dose range fulfilled the prescribed criteria for a satisfactory model. There was a good correlation between survival time and duration of coma, although survival time did not correlate with acetaminophen dose, peak plasma acetaminophen levels, thrombocytopenia, fall in hematocrit or fibrinogen, or alteration in other biochemical parameters. In addition to the unpredictable duration of survival and coma, the occurrence of acute anemia in 60% of the enzyme-induced animals detracted from the possible usefulness of this model to evaluate various therapeutic regimes.

1747 A STUDY OF THE PHYSICOCHEMICAL INTERACTIONS BETWEEN BILIARY LIPIDS AND CHLORPROMAZINE HYDROCHLORIDE: BILE-SALT PRECIPITATION AS A MECHANISM OF PHENOTHIAZINE-INDUCED BILE SECRETORY FAILURE.

(Eng.) Carey, M. C.; Hirom, P. C.; Small, D. M. (Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA 02115). *Biochem. J.* 153(3):519-531; 1976.

The physicochemical interactions of chlorpromazine hydrochloride [2-chloro-10-(3-dimethylaminopropyl)-phenothiazine hydrochloride] with the major components of bile were studied *in vitro* to determine its relation to bile secretory failure in man. Bile salts in concentrations above their critical micellar concentrations were precipitated from solution by chlorpromazine hydrochloride as insoluble 1:1 salt complexes. In the case of mixed bile salt/phosphatidylcholine micellar solutions, however, the degree of precipitation was inhibited by the phospholipid in proportion to its mole fraction. With increases in the concentration of chlorpromazine hydrochloride or bile salt, micellar solubilization of the precipitated complexes resulted. Sonicated dispersions of the negatively charged phospholipid phosphatidylserine were also precipitated, but dispersions of the zwitterionic phospholipid phosphatidylcholine were not. Chlorpromazine hydrochloride efficiently solubilized these membrane phospholipids as mixed micellar solutions when the drug:phospholipid molar ratio reached 4:1. Polarizing microscopy and x-ray diffraction studies revealed that the precipitated complexes were amorphous, and potentiometric studies confirmed the presence of a salt bond. Some dissociation of the complex occurred in the case of the most polar bile salt (K_s=0.365). As canalicular bile salt secretion determines much of bile-water flow, it is proposed that complexing and precipitating of bile salts by chlorpromazine hydrochloride and its metabolites may be physicochemically related to the reversible bile secretory failure produced by this drug.

1748 TOTAL AND PARTIAL ANOXIA OF THE LIVER: AN ATTEMPT TO CREATE PROTRACTED LIVER FAILURE IN THE PIG.

(Eng.) Tonnesen, K. (Rigshospi talet, Copenhagen, Denmark). *Scand. J. Gastroenter* 11(Suppl. 37):27-31; 1976.

Pig livers were exposed to partial or total anoxia for various periods in an attempt to produce severe, but non-lethal experimental liver failure. Group I (3 animals) was exposed to total anoxia for 30 min, group II (3 animals) for 50 min, group III (4 animal for 60 min, and group IV (3 animals) for 75 min. In group V (10 animals) a subtotal devascularization was performed. In groups I and II, all animals survived the period of observation (1 week). In gro III half of the animals, and in group IV (3) all of the animals died within 24 hr. In group V (10), 5 of the animals died with a mean survival time of 2 1/2 hr. The animals surviving the period of observa tion did show changes in the routine liver tests, bu none of them showed clinical signs of liver insufficiency. This indicates that the differences between lethal and clinically insignificant liver damage is very small. It is concluded that the pig liver can tolerate 50 min of total anoxia and recover almost completely after 1 week, and that a period of anoxia or subtotal devascularization does not create protracted liver failure.

1749 EFFECTS OF VASOCONSTRICTORS ON INTESTINAL VASCULAR RESISTANCE AND OXYGEN EXTRACTION.

(Eng.) Shepherd, A. P.; Pawlik, W.; Mailman, D.; Burks, T. F.; Jacobson, E. D. (Univ. Texas Health Science Center, Houston, TX 77025). *Am. J. Physiol.* 230(2):298-305; 1976.

The effects of vasoconstrictors on arteriovenous oxygen difference and on vascular resistance were measured in isolated constant-flow perfused canine small bowel to delineate the mechanism through which vasoactive compounds alter intestinal oxygen consumption and to determine the pharmacological nature of the involved receptors. Norepinephrine (NE, 0.6 μg/ml) and sympathetic stimulation (SS, 10 Hz) increased vascular resistance and depressed O_2 extraction. These effects were not altered by β-blockade, but were abolished by α-blockade. Since capillary filtration coefficients at constant-pressure perfusion and ^{86}Rb extraction at constant flow are reported to diminish during NE and SS, it follows that these agents reduce O_2 extraction by an α-adrenergic closure of precapillary sphincters. Vaso pressin (0.025 μg/ml) had similar effects, which were not affected by adrenergic blocking agents. Epinephrine (Epi), in high doses (0.9 μg/ml) or after propranolol, produced the same effects as NE and SS. By contrast, Epi in low doses (0.5 μg/ml) increased O_2 and ^{86}Rb extraction. This response to low doses of Epi was not affected by phentolamine, but it was reversed by propranolol. It is concluded that Epi in high doses or after propranolol depresses intestinal O_2 extraction by the same mechanism as NE and SS, but the mechanism through which Epi increases intestinal O_2 extraction in unclear.

1750 PANCREATIC, GALLBLADDER, AND GASTRIC RESPONSES TO INTRADUODENAL CALCIUM PERFUSION IN MAN. (Eng.) Holtermuller, K. H.; Malagelada, J.-R.; McCall, J. T.; Go, V. L. W. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Gastroenterology* 70(5):693-696; 1976.

The effect of intraduodenal calcium on pancreatic, gallbladder, and gastric functions was studied in 26 healthy male volunteers using a validated perfusion method to quantify total pancreatic, biliary, and gastric outputs during duodenal perfusion of either 6 mM, 12 mM, or 25 mM of elemental calcium (as isotonic calcium chloride solutions). Intraluminal calcium, 6 mM, significantly stimulated pancreatic trypsin output above basal rates, but had no effect on bilirubin output. Increasing calcium concentration to 12 mM and 25 mM, resulted in a significant increase in bilirubin output above basal levels, reflecting gallbladder emptying and contraction. The effect was similar to that achieved with an i.v. dose of cholecystokinin-pancreozymin (CCK-PZ) that produced "maximal" gallbladder contraction and pancreatic enzyme outputs. Responses to calcium were reproducible when repeated in the same individual. Gastric acid outputs and serum gastrin levels increased significantly only with higher calcium perfusions (25 mM). Although duodenal calcium perfusion (25 mM) slightly increased serum calcium concentrations, induced hypercalcemia (by i.v. calcium infusion) of similar magnitude had no effect on pancreatic or gallbladder function. It is suggested that intraduodenal calcium may induce release of CCK-PZ (and/or other neurohormonal factors) from the gut, causing stimulation of these digestive organs.

1751 RAT GASTRIC MUCOSAL OXYGEN TENSION, ULCER INDEX, PLASMA GASTRIN AND GLUCAGON FOLLOWING RESTRAINT STRESS. INFLUENCE OF VAGOTOMY, SPLANCHNICOTOMY AND EXOGENOUS SECRETIN. (Eng.) Schwille, P. O.; Schellerer, W.; Steiner, H.; Reitzenstein, M. (Chirurgische Universitatsklinik Mineralstoffwechsel- und Hormonlabor, Maximiliansplatz, D-8520 Erlangen, W. Germany). *Res. Exp. Med.* 167(2):149-158; 1976.

The effect of prior vagotomy, splanchnicotomy, or secretin administration on preserving intact gastric microcirculation (partial oxygen tension of gastric mucosa, pO_2) and on the ulcer index (UI) during stress was studied in male SPF Wistar rats. Stress ulceration was produced by restraint. Secretin was administered either during stress (5 times, 1, 2, 4, 5, 16 U/kg) or following the termination of the stress procedure (5 times, 4 or 8 U/kg). Truncal vagotomy, with and without pyloroplasty, or splanchnicotomy was performed 6-7 days prior to stress, in some animals. Neither prior truncal vagotomy, splanchnicotomy, nor combined dissection of abdominal autonomic nerves were effective in preventing the stress mediated fall of mucosal pO_2 and the rise in plasma glucagon. The UI remained elevated and gastrin was unchanged. Prophylactic injection of increasing doses of secretin maintained microcirculation at subnormal pO_2 levels for unstressed animals (V_{max} 15.53 mm Hg; K_m 0.99 U/kg), but simultaneously brought about a continuous rise in serum gastrin. Up to 8 U/kg, plasma glucagon was higher than in saline control groups, reaching a peak value with 2 U/kg when the UI showed its nadir. Following termination of stress, secretin therapy markedly improved both mucosal pO_2 and UI. It is suggested that breakdown of gastric microcirculation may not be solely responsible for stress ulcer development.

1752 FUNCTIONAL AND BIOCHEMICAL EVIDENCE OF DAMAGE TO ENTEROCYTES INDUCED BY TRIPARANOL: ROLE OF LYSOSOMES AND THE EFFECT OF A GLUTEN-FREE DIET. (Eng.) Soule, J.-C.; Neale, G.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 51 (1):19-25; 1976.

Functional and biochemical studies were performed on the small intestine of male Wistar rats given 0.114 mmol/kg of triparanol daily for 10 days, and the results were compared with those obtained in controls. The animals given triparanol were fed either standard rat food or a gluten-free diet. By using a recirculating-perfusion technique *in vivo*, it was shown that absorption of galactose from an 8 mM solution was impaired in the ileum but not in the jejunum of the triparanol-treated rats. Assays of marker enzymes for the principal subcellular organelles were performed on isolated jejunal and ileal enterocytes. In the ileum, there was a striking decrease in lysosomal enzyme activities and a smaller but significant decrease of lactate dehydrogenase, catalase, and malate dehydrogenase activities. In the jejunum, there was no significant change in the activities of these enzymes. Measurements of lysosomal integrity indicated that ileal lysosomal fragility was markedly increased and that jejunal lysosomes were affected to a much smaller extent. The results support the suggestion that triparanol causes damage by a mechanism similar to that operating in lysosomal storage diseases; this damage was not ameliorated by a gluten-free diet.

1753 HUMAN GASTRIC AND INTESTINAL RESPONSE TO MEALS: GENERAL DISCUSSION. (Eng.) Lagerlof, H. O.; Johansson, C. (No affiliation given). *Mt. Sinai J. Med.* 43:84-98; 1976.

1754 DISTRIBUTION OF DISACCHARIDASES, ALKALINE PHOSPHATASE, AND SOME INTRACELLULAR ENZYMES ALONG THE HUMAN SMALL INTESTINE. (Eng.) Asp, N.-G.; Gudmand-Hoyer, E.; Andersen, B.; Berg, N.-O.; Dahlqvist, A. (Dept. Nutrition, Univ. Lund, Lund, Sweden). *Scand. J. Gastroenterol.* 10(6):647-651; 1975.

See also, 1593, 1623, 1641, 1642, 1648, 1670, 1718, 1719, 1720, 1726, 1957, 2275.

DIAGNOSTIC PROCEDURES

1763 UPPER GASTROINTESTINAL ENDOSCOPY IN THE PEDIATRIC PATIENT. (Eng.) Tedesco, F. J.; Goldstein, P. D.; Gleason, W. A.; Keating, J. P. (Univ. Miami Sch. Medicine, P.O. Box 520875, Biscayne Annex, Miami, FL 33152). *Gastroenterology* 70(4):492-494; 1976.

The safety and effectiveness of performing upper gastrointestinal endoscopy without general anesthesia were evaluated in 50 children ranging in age from 9 months to 16 yr. Preparation of the subject included: (a) fasting for at least 8 hr, (b) administration of atropine sulfate (0.01 mg/kg) and meperidine (0.5-1.0 mg/kg), i.m., 30 min prior to the procedure, (c) use of cetacaine pharyngeal anesthesia, and (d) sedation with Diazepam (5-15 mg, i.v.). The Olympus GIF type D fiberscope was used for most patients over 9 yr of age, and the type P fiberscope was used for all other patients. The esophagus and stomach were visualized in their entirety and the duodenal bulb was entered in 40/46 patients. Of the 24 patients presenting with upper gastrointestinal bleeding, the source was identified by endoscopy in 20, and in 13 patients with either gastric or duodenal ulcers, 11 were diagnosed by endoscopy. The procedure usually required less than 20 min, and it caused no significant complications. Fiberoptic gastrointestinal endoscopy in children is a sensitive and safe diagnostic tool suitable for use without general anesthesia.

1764 EVALUATION OF SPECIFIC VALUE OF ENDOSCOPIC BIOPSIES AND BRUSH CYTOLOGY FOR MALIGNANCIES OF THE OESOPHAGUS AND STOMACH. (Eng.) Witzel, L.; Halter, F.; Gretillat, P. A.; Scheurer, U.; Keller, M. (Gastrointestinal Unit, Univ. Berne, Berne, Switzerland). *Gut* 17(5):375-377; 1976.

The value of multiple biopsies and brush cytology at esophago-gastroscopy was assessed in relation to macroscopic appearance and localization on 100 verified tumors in a prospective study. The cumulative accuracy achieved was 96%; this was significantly better ($p<0.01$) than that of biopsy (83%) and of cytology (85%). While the reliability of both procedures was not significantly different in malignancies of the esophagus, the gastric body, and the antrum, cytology was significantly more accurate in cancers of the cardia (90% and 55% resp., $p<0.05$). Cytology was also more reliable in stenosing tumors (92%/72%, $p<0.05$). In polypoid malignancies, a positive but not significant trend was found in favor of multiple biopsies (94% compared with 64%). One of the two early cancers was only diagnosed by cytology. The results confirm the high diagnostic accuracy of multiple endoscopic biopsies combined with brush cytology and demonstrate the value of cytology in stenosing tumors, especially in those of the cardia.

1765 HEARTBURN: THE ROLE OF RADIOLOGY. (Eng.) Wolf, B. S. (Mount Sinai Sch. Medicine, 5th Ave. and 100th St., New York, NY 10029). *JAMA* 235(12):1244-1247; 1976.

The importance of the radiologic demonstration of a hiatal hernia, reflux, or both, as the explanation of heartburn is discussed. Clinical-radiologic correlation requires additional observations such as the straightness of the potential path for reflux, the presence of a contractile esophagogastric region, the degree of extrinsic compression of the cuff of the stomach within the hiatus, the size of the hernia, and the peristaltic activity of the body of the esophagus. Vigorous or water-swallowing maneuvers to demonstrate reflux are unreliable in individual cases. The so-called patulous cardia, or effaced abdominal esophagus, or widened absent "submerged segment," is a variety of sliding hiatal hernia that is often neglected radiologically but may be of considerable clinical significance.

1766 SPECIFICITY OF ^{99m}Tc-PERTECHNETATE IN SCINTIGRAPHIC DIAGNOSIS OF MECKEL'S DIVERTICULUM: REVIEW OF 100 CASES. (Eng.) Berquist, T. H.; Nolan, N. G.; Stephens, D. H.; Carlson, H. C. (Mayo Clinic, 200 First St. S.W., Rochester, MN 55901). *J. Nucl. Med.* 17(6):465-469; 1976.

The use of abdominal scanning with pertechnetate in the diagnosis of Meckel's diverticulum, was evaluated by reviewing scintigrams and clinical data of 100 patients with suspected Meckel's diverticulum. Of the 100 patients, 33 underwent laparotomy, and Meckel's diverticulum was found in 8 patients. Meckel's diverticulum was correctly identified with pertechnetate scans before operation in seven of these eight cases. There was one false-negative study, in which only a small amount of intact gastric tissue remained in the diverticulum. Negative scans were correctly obtained in patients with arteriovenous malformations, intussusception, and hydronephrosis, all conditions previously suggested as possible causes of false-positive scans. Although this technique has certain limitations, its value as a noninvasive aid in the diagnosis of Meckel's diverticulum has been established.

1767 SERUM LYSOZYME LEVELS IN CROHN'S DISEASE AND ULCERATIVE COLITIS. (Eng.) Peeters, T. L.; Vantrappen, G.; Geboes, K. (Laboratorium voor Gastrointestinale Fysiopathologie, Katholieke Universiteit te Leuven, Leuven B-3000, Belgium). *Gut* 17(4):300-305; 1976.

Serum lysozyme levels were determined in 18 healthy volunteers, in 62 patients with Crohn's disease, and in 30 patients with ulcerative colitis. The mean concentration in Crohn's disease was significantly greater than in the other groups. In patients with Crohn's disease, as well as in patients with ulcerative colitis, the lysozyme levels correlated with the severity of the disease process and with the extent of the lesions; the more severe the disease and the more extensive the involvement, the higher the lysozyme levels. However, the lysozyme values of the different groups overlapped considerably. These results indicate that lysozyme determinations have only limited discriminative value for the diagnosis of Crohn's disease and for determining the severity and the extent of the disease process in the individual patient.

1768 UNUSUAL ROENTGEN MANIFESTATIONS OF LARGE BOWEL CANCER.

(Eng.) Seaman, W. B. (Coll. Physicians and Surgeons, Columbia Univ., 630 W. 168 St., New York, NY 10032). *Semin. Roentgenol.* 11(2):89-99; 1976.

Unusual roentgen manifestations of large bowel cancer are reviewed and illustrated. Calcification in colonic cancers is a rare event, occurring most often in patients under the age of 30. The calcifications are sometimes very opaque and discrete, but are more frequently faint and poorly defined. The correct diagnosis of perforating cancer of the colon is difficult for the radiologist because the roentgen appearance is dominated by the inflammatory component. The extensive pericolic inflammatory reaction produces a long smooth stricture with tapered margins; this is frequently mistaken for inflammatory disease. In others, the mucosal folds are swollen and many have a cobblestone appearance similar to that seen with granulomatous colitis. In cancer of the large bowel, when the neoplasm extends over a long segment, portions of the mucosa may be preserved due to submucosal invasion. Microscopically, these are scirrhous carcinomas. They are frequently undifferentiated and are not of the linitis plastica variety, which has a specific histologic appearance. Radiographically, they simulate an inflammatory process. Carcinoma is the predominant cause of colocolic intussusception in adults. A crescentic filling defect in the colon on barium enema should immediately suggest the diagnosis. If barium enters the lumen of the intussusceptum, the picture of narrow parallel folds surrounded by a stretched coil-like pattern of the intussuscipiens is pathognomonic.

1769 DETERMINATION OF LIVER VOLUME BY THE USE OF A GAMMA CAMERA CONNECTED WITH 1600 OR 4096 CHANNEL ANALYSER IN DIFFUSE LIVER.

(Eng.) Fujii, M.; Mukai, T.; Yamamoto, T.; Wakisaka, G. (Faculty of Medicine, Kyoto Univ., Kyoto, Japan). *Gut* 17(4):289-294; 1976.

A method of *in vivo* calculation of liver volume, using a gamma camera and a 1600 or 4096 channel analyzer, is described. Topographically, the maximum thickness, giving the highest counts in matrix data in the right anterior oblique projection, was measured as the maximum breadth in the right posterior oblique projection. Then the total counts given by the liver were transformed to the volume. Information obtained by the use of ^{198}Au-colloid at necropsy from 13 autopsies indicated that the errors were between -11.9 to +14.7%. In 20 normal control subjects, the mean of measured liver volumes was 779 ± 99 cm^3/m^2 of surface area. The volumetric calculation using ^{99m}Tc-Sn-colloid or ^{99m}Tc-phytate was compared with ^{198}Au-colloid in the same patients. The results wit ^{99m}Tc-Sn-colloid were well correlated with those wit ^{198}Au-colloid, but the results with ^{99m}Tc-phytate an ^{198}Au-colloid were almost equal. It is concluded th liver volume can be measured with reasonable accurac except in rare severe cases of liver cirrhosis.

1770 EFFECT OF VASOPRESSIN ON REGIONAL SPLANCHNIC BLOOD FLOWS IN CONSCIOUS MAN.

(Eng.) Erwald, R.; Wiechel, K. L.; Strandell, T. (Sodersjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 142(1):36-42; 1976.

The effect of a continuous i.v. infusion of lysine-8-vasopressin, (5 IU/70 kg/20 min) on the portal and the hepatic venous blood flow was studied in 11 conscious normovolemic patients with acute or chronic pancreatitis. The study was performed using multiple portal catheters, oxygen saturation measurements, and an indicator dilution technique with continuous infusion of ^{133}Xe into the portal vein or its tributaries. During vasopressin infusion, the total hepatic blood flow, estimated using indocyanine green dye, was reduced to 61% of the value at rest. The reduction in the portal venous blood flow during vasopressin infusion was more marked than the decrease of the total hepatic flow, corresponding to a calculated increase of the hepatic arterial flow of 50%. Total splanchnic oxygen uptake and extrahepatic splanchnic oxygen uptake were unchanged during and after infusion of vasopressin. Thus, changes in splanchnic blood flow were estimated from changes in arteriovenous oxygen differences. Also, a more pronounced reduction in the portal venous than of the hepatic venous blood flow was observed. The decrease during vasopressin infusion of the superior mesenteric venous flow was more marked than that of the splenic vein. The splanchnic circulatory changes may be different for other doses of vasopressin and in cirrhotic patients with higher hepatic arterial blood flow fractions.

1771 UTILIZATION OF THE QUANTITATIVE ASSAY OF LIPOPROTEIN X IN THE DIFFERENTIAL DIAGNOSIS OF EXTRAHEPATIC OBSTRUCTIVE JAUNDICE AND INTRAHEPATIC DISEASES.

(Eng.) Magnani, H. N.; Alaupovic, P. (Medical Sch., Univ. Birmingham, Birmingham B15 2TG, England). *Gastroenterology* 71(1):87-93; 1976.

Quantitative determination of LP-X, an abnormal serum low density lipoprotein, was performed on the sera of 620 patients with jaundice in the U.S. and in England. The results of serial assays over 5-8 days after patient admission to hospital or after onset of jaundice, if this occurred in hospital, correlated best with the type and management of jaundice. In some cases of early cholestatic disease of extrahepatic origin LP-X was absent, but after the observation period, it was found that only 1 of 81 patients with obstruction of the extrahepatic bile duct system remained negative. Of the remainder, 74 had or developed levels of LP-X exceeding 300 mg/100 ml. In addition, 43 of 49 subjects followed serially showed increases in LP-X concentration, with no change in 3 patients. Of 539 subjects with intrahepatic disease, 14 were LP-X positive and 27 of these had initial LP-X levels higher than 300 mg/100 ml. During the follow-up period, 35 of 47 patients with intrahepatic disease showed a reduction of LP-X; of the remaining 12 patients, 4 had mitochondrial antibody-positive primary biliary cirrhosis and 6 had severe cholestasis associated with acute infectious hepatitis and high aspartate transaminase levels. Similar figures for alkaline phosphatase showed less consistent changes during the follow-up period. The trends and absolute levels of LP-X, in addition to the use of similarly followed levels of the routine liver function tests, allowed better differentiation of jaundice requiring surgical correction from that remediable by medical means exclusively than did the use of the routine liver function tests alone. In addition, LP-X is specific for liver dysfunction whereas other routine liver function tests are not.

1772 DIAGNOSTIC USE OF PANCREATIC LIPASE DETERMINATION BY RADIAL ENZYME DIFFUSION, AND DESIGN OF A ROUTINE PANCREATIC PROFILE. (Eng.) Goldberg, J. M. (Stritch Sch. Medicine, Loyola Univ. Chicago, Maywood, IL 60153). *Clin. Chem.* 22(5): 638-642; 1976.

The possibility of using pancreatic lipase determination in the diagnosis of pancreatic disease was tested in 500 hospitalized patients. Radial enzyme diffusion revealed positive results for lipase in 8 patients with elevated serum urea or creatinine, in 7 patients with hyperglycemic fasting sera, in 3 bone fracture patients, and in 14 patients with pancreatitis. Selective screening of possible false positives revealed positive results in all of 30 sera from uremic patients with creatinine levels ranging between 17-140 mg/l, in 4 of 50 sera from hyperglycemic patients, and in 3 of 10 sera from bone fracture patients. In selected high-risk patients, no lipase activity was found in any of 85 patients without proven pancreatic disease or in 17 patients with biliary tree disease, but levels between 56 and 1,120 U/l were found in 22 patients with common duct edema, acute or chronic relapsing pancreatitis, or acute pancreatitis with common duct obstruction. It appears that determination of pancreatic lipase in serum, when used in conjunction with other tests, is useful in the diagnosis of pancreatic disease.

1773 THE INDICATIONS FOR AND DIAGNOSTIC VALUE OF PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY (PTC), ANGIOGRAPHY, AND COLONIC CONTRAST IN THE DIAGNOSIS OF BILIARY AND PANCREATIC DISEASE. (Ger.) Schmidt, M. (Stadtische Krankenanstalten, Nurnberg, Germany). *Therapiewoche* 25(27):3778-3786; 1975.

STOMACH

1841 THE MECHANISM OF HYPERGASTRINEMIA IN ACHLORHYDRIA: EFFECT OF FOOD, ACID, AND CALCITONIN ON SERUM GASTRIN CONCENTRATIONS AND COMPONENT PATTERN IN PERNICIOUS ANEMIA, WITH CORRELATION TO ENDOGENOUS SECRETIN CONCENTRATIONS IN PLASMA. (Eng.) Fahrenkrug, J.; Schaffalitzky de Muckadell, O. B.; Hornum, I.; Rehfeld, J. F. (Bispebjerg Hosp., Bispebjerg Bakke 23, DK-2400 Copenhagen NV, Denmark). *Gastroenterology* 71(1):33-37; 1976.

The effect of protein-rich food, i.v. calcitonin injections, and intragastric instillation of hydrochloric acid on serum gastrin concentrations and gastrin component pattern was studied in nine hypergastrinemic patients (pernicious anemia) and nine age- and sex-matched control subjects to determine the mechanism of hypergastrinemia. Plasma secretin concentrations were measured during intragastric acidification with 300 ml of 0.1 M HCl. The intragastric acidification resulted in a rapid fall in serum gastrin concentrations, although not below the upper limit of normal range. The small components, III (gastrin-17-like) and IV (gastrin-13-like), almost disappeared, whereas the concentrations of component I and component II (gastrin-34-like) were less affected. The increase in secretin concentrations after intragastric acidification was smaller in patients with pernicious anemia than in normal subjects, although the difference was not significant. In contrast to the results in normal control subjects, neither food nor calcitonin (0.7 Medical Research Council Units/kg, i.v.) produced significant variations in serum gastrin concentrations and gastrin component pattern of pernicious anemia pa-

LIBRARY U. OF I.

tients. The failure of food to stimulate and of calcitonin to inhibit release of gastrin in the majority of pernicious anemia patients suggests that gastrin secretion in these patients is autonomous. However, considering the recently recognized slow metabolic clearance rate of big gastrins, the effect of intragastric acidification suggests that the mechanism for acid inhibition of the antral gastrin secretion is intact in patients with achlorhydria.

1842 TISSUE PLASMINOGEN ACTIVATOR IN THE PATHOGENESIS OF PROTEIN-LOSING GASTROENTEROPATHY. (Eng.) Kondo, M.; Bamba, T.; Hosokawa, K.; Hosoda, S.; Kawai, K.; Masuda, M. (Kyoto Prefectural Univ. Medicine, Kawaramachi-Hirokoji, Kamikyo-ku, Kyoto 602, Japan). *Gastroenterology* 70(6):1045-1047; 1976.

Changes in tissue fibrinolytic activity were demonstrated in the digestive tract mucosa of patients with protein-losing gastroenteropathy. Two patients, a 25-yr-old man with hypertrophic gastritis and a 40-yr-old man with Menetrier's disease, had hypoproteinemia, and their mucosal fibrinolysis was increased (120 mm^2 and 46 mm^2, resp.) in comparison to that of 30 healthy subjects (range, 10-36 mm^2). Antiplasmin therapy with p.o. trans-4-aminoethyl cyclohexane carboxylic acid (2.25-3 g/day, for 4 months) dramatically increased serum protein and decreased tissue fibrinolytic activity in both patients. Antiplasmin also increased serum protein levels in three other patients, including a woman with Crohn's disease. Antiplasmin therapy produced no response in a man with normal fibrinolytic activity and hypoproteinemia associated with intestinal lymphangiectasia. These observations suggest that activation of the fibrinolytic system in the digestive mucosa may play an important role in the pathogenesis of protein-losing gastroenteropathy.

1843 PRECANCEROUS CHANGES IN THE STOMACH. (Eng.) Kawachi, T.; Kurisu, M.; Numanyu, N. Sasajima, K.; Sano, T.; Sugimura, T. (Natl. Cancer Center Res. Inst., Tsukiji, Chuo-ku, Tokyo, Japan). *Cancer Res.* 36(7):2673-2677; 1976.

A method for visualizing disaccharidases using Tes-Tape was developed to investigate the relation between intestinal metaplasia and gastric carcinoma. This method was applied to over 130 specimens of stomach surgically removed for the treatment of gastric carcinoma. Intestinalization was classified into types I and II intestinal metaplasia. In type I, sucrase, maltase, trehalase, alkaline phosphatase, goblet cells, and Paneth cells were present. In type II, sucrase and maltase were present, but alkaline phosphatase and trehalase were absent. In type II, goblet cells were present but Paneth cells were absent. Some of the villi with goblet cells in the area of intestinalization in the stomach were not stained by sucrase activity, although most of the villi were stained. The presence of a third type of metaplasia was suggested. Purified sucrases obtained from the intestine and one case of type I intestinal metaplasia showed blood group reactivity due to the oligosaccharide side chain. However, purified sucrases obtained from two cases of type II intestinal metaplasia were negative in blood group reactivity. A high content of α-fetoprotein was demonstrated in the areas with intestinal metaplasia surrounding cancer. However, it was not detected or its content was very low in poorly differentiated and in anaplastic cancers. The content of α-fetorptein in intestinal metaplasia surrounding these types of gastric carcinoma was also low. The findings supoort the idea that intestinalization is closely related to the development of stomach cancer.

1844 IMMUNOCHEMICAL STUDY AND CELLULAR LOCALIZATION OF HUMAN PEPSINOGENS DURING ONTOGENESIS AND IN GASTRIC CANCERS. (Eng.) Hirsch-Marie, H.; Loisillier, F.; Touboul, J. P.; Burtin, P. (Faculte de Medecine, Saint-Antoine, Paris, Franc *Lab. Invest.* 34(6):623-632; 1976.

Gastric pepsinogens were studied in gastric mucosa from 22 patients without cancer, in stomach from 48 fetuses (8-38 weeks), and in tissue from 17 patients with gastric carcinoma. In noncancerous adult mucosa, immunoenzymologic methods showed that pepsinogen II (previously called Pg I-II) was found mostly in fundic or mediogastric extracts, whereas Pg IV was predominant in antropyloric extracts. Pg II was localized by immunofluorescence techniques in the chief cells of deep glands found near the muscularis. Pg III was present in the superficial zone of deep glands and Pg IV was found in the surface epithelium and in the superficial glands of the mucosa. In fetal stomach, only Pg IV ("fetal pepsinogen") was identified by standard immunoelectrophoresis. It was localized by immunofluorescence in the superficial epithelium. However, bidimensional immunoelectrophoresis and immunofluorescence did reveal low levels of Pg II and Pg III by the eighth or ninth week of ontogenesis. Pg II and Pg III were localized in the rudimentary glands near the superficial epithelium. Important differences were noted when gastric carcinomas were compared with normal mucosa. Pg II or Pg III were often absent in the tumor extracts, but Pg IV was regularly and, at times, exclusively identified regardless of the location of the tumor. Pg IV was often the only pepsinogen that was characterized in dedifferentiate cancerous cells by immunofluorescence; this was also true of the calciform cells of some metaplastic gastric mucosa. Pg III was observed rarely, and Pg II never, in cancerous cells. The biochemical modifications of the cancerous tissue closely resemble those of fetal tissue.

1845 GASTRIC ULCERS IN THE FUNDIC GLAND AREA. (Eng.) Tatsuta, M.; Okuda, S. (Center for Adult Diseases, Osaka, Japan). *Gastroenterology* 71(1):16-18; 1976.

The endoscopic Congo red test was performed on 216 patients with gastric ulcers (232 lesions) to examine the relation between gastric ulcers and acid-secreting areas. Eighteen of the ulcers examined (7.8%) were surrounded by an acid-secreting area (fundic gland area). Histological examination of specimens obtained by gastrectomy also showed that five of the lesions examined (4.5%) were located in the fundic gland area. Ulcers in the fundic gland area were found most frequently in the angulus and lower gastric body, adjacent to the acid-secreting boundary. These ulcers were associated with little or no fundal gastritis, whereas ulcers in the pyloric gland area were usually associated with moderate or severe fundal gastritis. Unlike ulcers of similar depth in the pyloric gland area, ulcers surrounded by normal fundic mucosa healed rapidly and completely. No recurrence of these ulcers was seen in a 1-yr endoscopic follow-up period. This study demonstrates that peptic ulcers can be found in the fundic mucosa in contrast to previous findings that the fundic mucosa is resistant to HCl and that peptic ulcers never develop in this region. Two hypotheses concerning the etiology of this type of ulcer are discussed: (a) severe superficial changes at the onset of ulceration disturbed the acid-secreting function of the fundic mucosa adjacent to the acid-secreting boundary; and (b) the normal fundic mucosa may undergo ulceration due to disturbance of blood vessels in the gastric mucosa.

1846 EFFECT OF HISTAMINE H_2-RECEPTOR BLOCKADE ON GASTRIC EMPTYING AND SERUM GASTRIN IN MAN.

(Eng.) Forrest, J. A. H.; Heading, R. C.; Park, J.; Carter, D. C.; Lennon, J.; Lidgard, G.; Shearman, D. J. C. (Royal Infirmary, Edinburgh, Scotland). *Scott. Med. J.* 21(1):23-27; 1976.

The effect of p.o. administered metiamide on the rate of gastric emptying was assessed in 24 uncomplicated duodenal ulcer patients given a standard meal containing indium 113m DTPA chelate; the effect of metiamide on the serum gastrin response to a protein meal was also studied in 7 healthy men. Metiamide (four 100-mg tablets) produced a significant slowing of gastric emptying when compared with control studies performed on the same patients following p.o. administration of a placebo. Paired experiments demonstrated that a significantly greater elevation of serum gastrin occurred after metiamide than after placebo in the seven volunteers. The delay in gastric emptying produced by metiamide may be mediated by an elevation of the serum gastrin concentration. In patients with peptic ulcer disease, this could lead to a rebound in gastric acid secretion and recurrence of peptic ulceration when the drug is stopped.

1847 TREATMENT OF STRESS-INDUCED UPPER GASTROINTESTINAL/HAEMORRHAGE WITH METIAMIDE.

(Eng.) MacDonald, A. S.; Steele, B. J.; Bottomley, M. G. (Dalhousie Clinical Res. Center, 5849 University Ave., Halifax, Nova Scotia, B3H 4H7, Canada). *Lancet* 1(7950):68-70; 1976.

The H2-blocking antihistamine metiamide was used to treat 14 episodes of bleeding from the stomach or duodenum in 11 patients. In 11 instances, bleeding was due to erosive gastritis or duodenitis. It promptly ceased after administration by gastric tube of one or two doses of 300 mg metiamide at 6-hr intervals and it did not recur as long as the drug was continued. In the two instances in which the bleeding continued, chronic ulcers eroded into major blood vessels. There were no complications from the drug even in five patients with severe bone marrow suppression after renal transplantation. Metiamide seems to be a safe and highly effective agent in the control of bleeding due to erosive gastritis.

1848 HEALING OF GASTRIC ULCER DURING TREATMENT WITH CIMETIDINE.

(Eng.) Pounder, R. E.; Stekelman, M.; Hunt, R. H.; Milton-Thompson, G. J.; Misiewicz, J. J. (Central Middlesex Hosp., London, NW10 7NS, England). *Lancet* 1(7955):337-339; 1976.

Ten patients with benign gastric ulcer were treated with cimetidine (0.8 or 1.6 g/day) for 6 weeks to determine its effect on healing. Weekly examinations revealed rapid relief of symptoms. At the end of treatment, endoscopy showed that all the ulcers had healed. Healing was not associated with an improvement of acute atrophic gastritis or with any change of gastric mucosal potential difference. No untoward clinical or laboratory effects were observed. The results suggest that cimetidine be used in controlled trials in patients with gastric ulcer.

1849 EFFECT OF METOCLOPRAMIDE IN CHRONIC GASTRIC RETENTION AFTER GASTRIC SURGERY.

(Eng.) Metzger, W. H.; Cano, R.; Sturdevant, R. A. L. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA). *Gastroenterology* 71(1):30-32; 1976.

The effect of metoclopramide on gastric emptying was tested in six patients with chronic gastric retention after vagotomy and gastric resection. Gastric emptying was measured using a gamma camera technique and a solid meal labeled with ^{99m}technetium-labeled diethylenetriaminepentaacetic acid. Metoclopramide (10 mg, i.m.) produced a 2.6-fold increase in gastric emptying in the first 90 min after eating the meal, compared to placebo ($p<0.01$). Metoclopramide did not alter gastric emptying in eight normal volunteers. These data indicate that metoclopramide may be useful in treatment of patients with chronically impaired gastric emptying after gastric surgery.

1850 BILE-INDUCED ACUTE EROSIVE GASTRITIS: ITS PREVENTION BY ANTACID, CHOLESTYRAMINE, AND PROSTAGLANDIN E_2.

(Eng.) Mann, N. S. (Veterans Admin. Hosp., 800 Zorn Ave., Louisville, KY 40202). *Am. J. Dig. Dis.* 21(2):89-92; 1976.

Experiments were conducted to determine whether the intragastric administration of whole bile (2.0 ml/

LIBRARY U. S.

hr, 4 times) produced acute erosive gastritis in rats, and if this could be prevented by concomitant intragastric administration of an antacid (Maalox, 1 ml/hr, 4 times), cholestyramine (0.5 g in 2.0 ml saline/hr, 4 times), or prostaglandin E_2 (1 mg in 1.0 ml saline/hr, 4 times). Microscopic examination confirmed the presence of superficial mucosal ulceration and submucosal congestion and hemorrhage in the animals treated with bile only. The number of acute erosions was significantly reduced in the animals treated with one of the three test substances ($p<0.001$), and prostaglandin E_2 seemed more effective than Maalox or cholestyramine. The results demonstrate that the administration of whole bile produces erosive gastritis in rats and that the concomitant intragastric administration of an antacid, a bile salt binding resin, and a prostaglandin is effective in preventing this type of experimental acute erosive gastritis.

1851 GASTRIC INFARCTION AFTER THERAPEUTIC EMBOLIZATION. (Eng.) Bradley, E. L., III; Goldman, M. L. (Emory Univ. Sch. Medicine, 69 Butler St., S.E., Atlanta, GA 30303). *Surgery* 79(4):421-424; 1976.

The limitations of therapeutic transcatheter embolization of the gastric artery are illustrated in the case of a 62-yr-old woman who was treated for recurrent massive upper gastrointestinal hemorrhage. Angiography revealed a point source in the distribution of the left gastric artery. Bleeding continued despite pitressin infusion, and a specific bleeding point could not be found. Vagectomy, pyloroplasty, and gastrostomy were performed; splenectomy was also necessary, as the splenic capsule was torn during surgery. Embolization of the left gastric artery was performed, using fragments of absorbable gelatin sponge, together with pitressin infusion (0.2 U/min, 10 hr). Twelve days later, a dehiscence of the superior aspect of the wound revealed extensive gastric necrosis; postmortem examination revealed that the entire cardia and fundus were absent. The ischemic gastric necrosis in this patient was thought to be secondary to failure of collateral circulation after embolic occlusion of the left gastric artery and pitressin infusion. Exploration of the posterior aspect of the stomach through the gastrocolic omentum and the incidental splenectomy resulted in the loss of the majority of gastroepiploic arterial supply. It is suggested that selective embolization be reserved for patients who cannot be controlled on pitressin infusion and who represent prohibitive surgical risks.

Stomach

Peptic Ulcers

1884 GASTRIC AND DUODENAL ULCER AND THEIR ASSOCIATED DISEASES. (Eng.) Langman, M. J. S.; Cooke, A. R. (City Hosp., Nottingham NG5 1PB, U.K.). *Lancet* 1(7961):680-683; 1976.

The relation between gastric and duodenal ulcer and their associated diseases is discussed. Assessments of likely associations are hindered by the frequent lack of controls, by controls that are inadequate, by inadequate descriptions of techniques, and by inherent biases in some of the techniques. Ulcer is unusually frequent in patients undergoing treatment for chronic renal failure. It is possibly more frequent in association with hyperparathyroidism and in cirrhosis, in cardiovascular disease (except hypertension), and in chronic respiratory disease. The authors conclude that there is insufficient evidence for other associations.

1885 PYLORIC-SPHINCTER STUDIES IN PEPTIC-ULCER PATIENTS. PYLORUS IN PEPTIC ULCER. (Eng.) Valenzuela, J. E.; Defilippi, C. (Veterans Admin. Wadsworth Hosp. Center, Building 115, Room 115, Los Angeles, CA 90073). *Am. J. Dig. Dis.* 21(3):229-232; 1976.

Pyloric pressure was assayed by a manometric procedure in the basal state and 10 min after intraduodenal infusion of 0.1 N HCL in 13 control subjects, 11 patients with benign gastric ulcer, 8 patients with duodenal ulcer, and 2 patients with coexistent gastric and duodenal ulcers. Mean resting pyloric pressure in gastric ulcer patients (5.17 mm Hg) was significantly lower than in controls (9.40 mm Hg) and it did not increase after HCl perfusion into the duodenum. Mean basal pyloric pressure in duodenal ulcer patients (11.30 mm Hg) did not differ significantly from controls and it increased after intraduodenal perfusion of HCl to 15.72 mm Hg. The two patients with coexistent ulcers had manometric patterns similar to those of gastric ulcer patients. Decreased pyloric sphincter pressure in gastric ulcer patients may be the mechanism responsible for the increased duodeno-gastric reflux observed in these patients.

1886 PERFORATED PEPTIC ULCER LONG-TERM FOLLOW-UP. (Eng.) Hennessy, E. J.; Chapman, B. L.; Duggan, J. M. (Royal Newcastle Hosp., Newcastle, New South Wales 2300). *Med. J. Aust.* 1:50-53; 1976.

A series of 349 survivors of perforated peptic ulcer was followed for periods of up to 23 yr. Almost 9 out of every 10 patients suffered from dyspepsia during follow-up. Subsequent elective gastroduodenal surgery was required in more than 25% of the cases. The surgery rate for gastric ulcer was more than 1.5 times that for pyloroduodenal ulcer, and for females it was almost double that for males. The highest rate of all was for females with gastric ulcer, almost 50% of them underwent surgery. One in 5 patients bled during follow-up; 1 in 8 developed stenosis of the stomach or duodenum; and 1 in 11 perforated again. There was a significantly increased incidence of subsequent perforation and stenosis in those patients with an initial perforation of 5 mm or more in diameter. Gastric carcinoma occurred in less than 2% of the cases and was restricted to cases of pyloroduodenal perforation. When complications occurred, the majority did so within 5 yr. Of the 262 patients about whom complete information was available, only 15% had no complications on follow-up. The indications for definitive surgery at perforation should be extended to include perforated gastric ulcer in the female, particularly if the ulcer is large.

1887 GASTRIC PROSTAGLANDIN E OUTPUT DURING BASAL AND STIMULATED ACID SECRETION IN

NORMAL SUBJECTS AND PATIENTS WITH DUODENAL ULCER. (Eng.) Cheung, L. Y.; Jubiz, W.; Moore, J. G. (Univ. Utah Medical Center, 50 North Medical Drive, Salt Lake City, UT 84132). *J. Surg. Res.* 20(4):369-372; 1976.

Prostaglandin E (PGE) output into the gastric lumen under basal conditions and after insulin hypoglycemia was studied in four normal subjects and in eight patients with uncomplicated duodenal ulcers. In both groups, increased acid secretion following vagal stimulation was accompanied by a rise in PGE output, as determined by radioimmunoassay. This observation, together with the known inhibitory effect on acid secretion, supports the concept that synthesis and local release of PGE may play a regulatory role. The fact that patients with ulcer disease have a slightly higher PGE output in gastric juice during basal and stimulated acid secretion does not support the hypothesis that PGE deficiency is an underlying mechanism in the pathogenesis of acid peptic disease.

1888 THE EFFECT OF BETAZOLE ON SERUM GROUP I PEPSINOGEN LEVELS: STUDIES IN SYMPTOMATIC PATIENTS WITH AND WITHOUT RECURRENT ULCER AFTER VAGOTOMY AND GASTRIC RESECTION OR DRAINAGE.

(Eng.) Samloff, I. M.; Secrist, D. M.; Passaro, E., Jr. (Harbor General Hosp., 1000 W. Carson St., Torrance, CA 90509). *Gastroenterology* 70(6):1007-1013; 1976.

The effect of betazole (1.5 mg/kg body weight) on serum group I pepsinogen (PG) levels was investigated in 50 symptomatic postoperative patients (20 with and 30 without recurrent ulcer), after either a vagotomy and gastric resection or a drainage procedure. In patients with recurrent ulcer, mean serum PG I levels increased after betazole and reached a maximum of 116.5 ± 2.2% (SE) of basal at 2 hr. Mean levels were significantly greater than basal at 1 hr ($p<0.01$) and at 90 and 120 min ($p<0.001$). In contrast, the basal level was significantly less ($p<0.001$) in patients with no recurrent ulcer than in patients with recurrent ulcer. Mean serum PG I levels decreased in patients without recurrent ulcer and reached a nadir of 75.0 ± 4.3% of basal at 2 hr. All 20 patients with recurrent ulcer and 5 patients without recurrence had a 2-hr serum PG I level of more than 98% of basal. A 2-hr serum PG I level of more than 98% of basal was also correlated with a vagotomy and drainage; a peak acid output of more than 11 mEq/hr ($p<0.001$), and a positive insulin test, with a level of less than 92% of basal, was correlated with a vagotomy and gastric resection, a peak acid output of less than 11 mEq/hr, and a negative insulin test. Basal serum PG I and serum gastrin levels were significantly higher ($p<0.001$) in patients with the former type of PG I response. The results indicate that betazole has a differential effect on serum PG I levels in symptomatic postoperative patients with and without recurrent ulcer.

1889 THE EFFECT OF CIMETIDINE, A NEW HISTAMINE H_2-RECEPTOR ANTAGONIST, ON MEAL-STIMULATED ACID SECRETION, SERUM GASTRIN, AND GASTRIC EMPTYING IN PATIENTS WITH DUODENAL ULCER.

(Eng.) Richardson, C. T.; Walsh, J. H.; Hicks, M. I. (Univ. Texas Health Science Center Dallas, Dallas, TX). *Gastroenterology* 71(1):19-23; 1976.

The effect of cimetidine on meal-stimulated acid secretion, measured by *in vivo* intragastric titration, was studied in nine patients with duodenal ulcer. Meal-stimulated acid secretion was progessively inhibited by increasing p.o. doses of cimetidine (25-400 mg). Four hundred mg suppressed acid secretion by 73% for the first 3 hr after the meal, whereas it inhibited acid secretion by 94% during the 30-min period of maximal inhibition. The dose of cimetidine required to suppress acid secretion by 50% during the 30-min period of maximal inhibition was 25 mg. The duration of action of a 300-mg dose was at least 7 hr. Cimetidine was equally effective in inhibiting meal-stimulated acid secretion at two physiological intragastric pH levels (5.0 and 2.5). It had no effect on serum gastrin concentration when intragastric pH was maintained at 5.0, but when pH was allowed to seek its own level, serum gastrin concentration was higher after cimetidine than after placebo. This probably occurred because of decreased acid secretion, and therefore decreased total acid, after cimetidine. Cimetidine had no effect on gastric emptying, and no side effects were noted in any patients. These experiments demonstrate that cimetidine is as effective an acid inhibitor as metiamide.

1890 CIMETIDINE SUPPRESSION OF NOCTURNAL GASTRIC SECRETION IN ACTIVE DUODENAL ULCER.

(Eng.) Longstreth, G. F.; Go, V. L. W.; Malagelada, J. R. (Gastroenterology Unit, Mayo Clinic, Rochester, MN 55901). *N. Engl. J. Med.* 294(15):801-804; 1976.

The antisecretory effects of cimetidine, an H2-receptor antagonist, were investigated in eight men with active duodenal ulcers. Doses of 200, 300, or 400 mg were taken p.o. at bedtime. In all cases, cimetidine depressed acid output and profoundly increased intragastric pH within 1 hr of digestion. Anacidity ($pH \geq 7.0$) was obtained in five of the six patients who received 400 mg and in five of the six patients who were given 300 mg, but in none of the four patients who were given 200 mg. The 400 and 300 mg doses caused a significant overall (12 midnight to 7 a.m.) decrease in acid output ($p<0.001$) and an increase in intragastric pH ($p<0.01$). The 200 mg dose caused no significant changes in acid output and had only a borderline effect on pH. The relation of dose to effect differed significantly among patients ($p<0.001$). Cimetidine caused a substantial decrease in secretory volume output. Doses of 400, 300, and 200 mg produced significant effects on overall secreted volume ($p<0.01$, $p<0.01$, and $p<0.02$, resp.), but no significant difference was found among doses. Dose related increases of drug blood levels were observed and correlated with the degree and duration of acid output inhibition.

LIBRARY U. OF I. URBANA-CHAMPAIGN

Serum gastrin levels were unaffected, and no significant correlation was found between total bile acid refluxed and total acid output. Cimetidine had no effect on serum gastrin values. It is concluded that cimetidine appears to be a potent inhibitor of nocturnal gastric secretion.

1891 INHIBITION OF NOCTURNAL ACID SECRETION IN DUODENAL ULCER PATIENTS BY AN H-2 HISTAMINE ANTAGONIST--CIMETIDINE: A CONTROLLED DOUBLE-BLIND INVESTIGATION. (Eng.) Hollander, D.; Hossain, Z.; Sufi, A. M. (Scott Hall of Basic Medical Services, Wayne State Univ., Detroit, MI 48201). *Am. J. Dig. Dis.* 21(5):361-365; 1976.

The ability of cimetidine to suppress overnight gastric acid secretion was tested in eight male duodenal ulcer patients. In a double-blind controlled investigation, each volunteer was studied during four consecutive nights. In randomized order they received either 100-, 200-, or 300-mg cimetidine tablets or a placebo. No clinical or laboratory side effects of the drug were found. Single-dose p.o. administration of 300 mg cimetidine caused a significant ($p<0.05$) inhibition of overnight gastric acid secretion for an 8-hr period, with the intragastric pH remaining between 3.5-6.0. Because of its potent gastric acid inhibitory effect, cimetidine may become an important therapeutic agent in the management of peptic ulcer disease.

1892 EFFECT OF SYNTHETIC 15-METHYL ANALOG OF PGE_2 ON GASTRIC ACID AND SERUM GASTRIN RESPONSE TO PEPTONE MEAL, PENTAGASTRIN, AND HISTAMINE IN DUODENAL ULCER PATIENTS. (Eng.) Konturek, S. J.; Oleksy, J.; Biernat, J.; Sito, E.; Kwiecien, N. (Inst. Physiology, 31-531 Krakow, Grzegorzecka 16, Poland). *Am. J. Dig. Dis.* 21(4):291-295; 1976.

The effect of 15(S) 15-methyl prostaglandin E_2, methyl ester (15-ME-PGE_2, 0.5 μg/kg/hr, i.v.) on gastric secretion and serum gastrin level was studied in six duodenal ulcer patients. 15-Me-PGE_2 caused an immediate and almost complete inhibition of basal gastric acid and pepsin secretion. Acid secretion, induced by a peptone meal and determined by an intragastric titration technique, was almost as high as the maximal response to histamine and it was accompanied by a significant rise in serum concentration of immunoassayable gastrin. 15-Me-PGE_2 caused a sudden and complete inhibition of gastric acid response to a peptone meal. 15-Me-PGE_2 did not significantly affect serum gastrin levels under basal conditions and in response to a peptone meal. Gastric acid and pepsin outputs induced by maximal stimulation with pentagastrin (4 μg/kg-hr) were inhibited by 15-Me-PGE_2 by about 70% and those induced by histamine were inhibited by about 45%. After the withdrawal of 15-Me-PGE_2 infusion, gastric secretion remained reduced for the duration of the test. It is concluded that 15-Me-PGE_2 is a very strong inhibitor of gastric acid and pepsin secretion induced by various secretory stimuli, particularly under basal conditions and in response to a meal. In view of its prolonged inhibitory activity, 15-Me-PGE_2 may have clinical potential in the treatment of peptic ulcer disease.

1893 INHIBITION OF GASTRIC SECRETION BY EXOGENOUS SECRETIN AND CHOLECYSTOKININ IN NORMALS AND DUODENAL ULCER PATIENTS. (Eng.) Jorgensen S. P.; Henriksen, F. W. (Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):39-42; 1976.

The inhibitory effect of combined secretin (0.5 and 1.0 clinical U/kg/hr) and cholecystokinin (0.5 and 1.0 Ivy dog U/kg/hr) on the pentagastrin-stimulated (0.15-1.0 and 6.0 μg/kg/hr) gastric secretion in 12 normal volunteers was compared with that in 12 duodenal ulcer patients. Regardless of the dose level, the gastric secretion of fluid and acid was inhibite to the same extent in the normal subjects as in the duodenal ulcer patients, indicating that a decreased sensitivity to secretin and cholecystokinin is not a pathogenetic factor for the development of duodenal ulcer.

1894 EFFECT OF SECRETIN ON GASTRIC FUNCTION IN NORMAL SUBJECTS AND IN PATIENTS WITH DUODENAL ULCER. (Eng.) Dalton, M. D., Eisenstein, A. M.; Walsh, J. H.; Fordtran, J. S. (Univ. Texas Southwestern Medical Sch., 5323 Harry Hines Blvd., Dallas, TX 75235). *Gastroenterology* 71(1): 24-29; 1976.

The effect of constant i.v. infusion of secretin (0.25, 0.50, 1.50, and 3.0 μg/kg/hr) on meal-stimula ed acid secretion was measured by *in vivo* titration to pH 5.0 in seven normal subjects and in two men with exocrine pancreatic insufficiency due to chroni alcoholism. The pattern and degree of secretin inhibition of food-stimulated acid secretion depended upon when the secretin infusion was begun; the effect was more pronounced when the secretin was begun 1 hr before the test meal than when the meal and secretin infusions were begun simultaneously. I hibition of acid secretion in the normal subjects was approximately the same as in the patients with pancreatic exocrine insufficiency who could secrete only small amounts of pancreatic bicarbonate in response to secretin. Secretin at 0.25 and 0.5 μg/kg/hr inhibited acid secretion only slightly, whereas 3.0 μg/kg/hr completely stopped acid secretion. Inhibition of acid secretion by secretin was similar in controls and in patients with duodenal ulcer. Secretin also reduced the rise in serum gastrin concentration after the meal and delayed gastric emptying; both responses were approximately the same in normals and in duodenal ulcer patients. Secretin inhibited basal gastric acid secretion but had no consistent effect on basal serum gastrin concentration.

SMALL INTESTINE

1933 ON DIPEPTIDASE ACTIVITY IN SMALL INTESTINAL MUCOSA IN PATIENTS WITH CHRONIC NONSPECIFIC ENTERITIS. (Bul.) Nikolov, N.; Nedkova-Bratanova, N.; Ivanov, E.; Krusteva, A.; Lozanova, L.; Bozijanov, V.; Milev, N. (Inst. Gastroenterology, Bulgaria). *Vutr. Bol.* 14(1):11-16; 1975.

Dipeptidase activity in homogenate form from small intestinal mucosa was determined in 45 patients (25 women, 19 men) with chronic nonspecific enteritis. Control patients had peptic ulcer and chronic alcoholism without intestinal disease and normal small intestinal mucosa. Most enzymes belonged to the endopeptidase group, splitting the dipeptides into the neutral amino acids: glycyl-l-alanine, alanyl-l-valine, alanyl-l-isoleucine, alanyl-glycine, leucyl-l-leucine, alanyl-l-leucine, alanyl-l-proline, glycyl-l-glutamic acid; only one enzyme, glycyl-l-leucine, belonged to enzymes of the brush border enterocytic zone. The mean values of dipeptidase activity in chronic nonspecific enteritis were decreased significantly in comparison with the mean values obtained from control patients. Glycyl-l-alanine activity was decreased by 49.2%, glycyl-l-leucine by 33.2%, glycyl-l-valine by 19.6%, glycyl-l-isoleucine by 61%. In most cases, decreased enzyme activity was proportional to the severity of the disease and to the degree of histologic changes. However, it was not decreased to the level found in patients with celiac sprue. In some cases, enzyme activity did not correspond to morphological changes: normal mucosa and decreased peptidase activity coexisted in six patients, and normal or elevated peptidase activity was found together with partial mucosal atrophy in two cases. The findings suggest that these enzymes are significant for pathogenetic digestive and resorptive disturbances, especially for protein disturbances in chronic nonspecific enteritis.

1934 ARTERIOVENOUS MALFORMATIONS OF THE GASTROINTESTINAL TRACT. (Eng.) Moore, J. D.; Thompson, N. W.; Appelman, H. D.; Foley, D. (Dept. Surgery, Univ. Michigan, Ann Arbor, MI 48104). *Arch. Surg.* 111(4):381-388; 1976.

Seventeen patients (7 months-81 yr) who were diagnosed over an 8-yr period as having arteriovenous malformations (AVM's) of the gastrointestinal tract complicated by major hemorrhage are reviewed; seven case reports are presented. A clinical classification of AVM's was developed, based on angiographic characteristics, localization, age of the patient, and family history. Type 1 AVM's were solitary, localized lesions within the right side of the colon. They occurred in seven patients, 55 yr of age or older. None were palpable or visible at operation. Type 2 AVM's occurred in seven patients. They were larger and were occasionally visible in the small intestine; they were probably of congenital origin. All symptoms began before the patients were 50 yr of age. Type 3 AVM's were punctate angiomas causing gastrointestinal hemorrhage. They occurred in three patients with the classical findings of hereditary hemorrhagic telangiectasia. Most AVM's can be diagnosed preoperatively only by selective angiographic studies.

1960 NON-SPECIFIC CYTOTOXICITY OF WHEAT GLIADIN COMPONENTS TOWARDS CULTURED HUMAN CELLS. (Eng.) Hudson, D. A.; Cornell, H. J.; Purdham, D. R.; Rolles, C. J. (Inst. Child Health, Nuffield Building, Francis Rd., Birmingham B16 8ET, England). *Lancet* 1(7955):339-341; 1976.

Fractions of a proteolytic digest of wheat gliadin were assayed for cytotoxic properties using cultured human embryonic intestinal, lung, kidney, adrenal, and HEp-2 cells. Separation of the gliadin digest into 10 major fractions was achieved by chromatography on SP-Sephadex C-25. In all cell types, noxious effects were observed microscopically over a 24-hr period. The most active fraction was that previously shown to produce xylose malabsorption in subjects with celiac disease, disruption of lysosomes and inhibition of morphological recovery of cultured mucosa from a patient on a gluten-free diet. The authors suggest that the demonstration of nonspecific cytotoxic properties associated with some of the products of gliadin digestion may be useful for defining the minimum chemical structure that can be produced *in vitro* that results in deleterious effects when fed to patients with celiac disease.

1961 GLUTEN-SENSITIVE ENTEROPATHY: INHIBITION BY CORTISOL OF THE EFFECT OF GLUTEN PROTEIN IN VITRO. (Eng.) Katz, A. J.; Falchuk, Z. M.; Strober, W.; Shwachman, H. (Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA 02115). *N. Engl. J. Med.* 295(3):131-135; 1976.

To investigate the pathogenesis of gluten-sensitive enteropathy, the effect of cortisol was analyzed in cultures of jejunal specimens obtained by biopsy in 11 patients with the disease, in 1 patient with dermatitis herpetiformis and malabsorption, in 1 patient with non-gluten-sensitive gastrointestinal disease, and in 5 normal subjects. Cultures were prepared with and without gluten or cortisol (5 μM). Morphology and alkaline phosphatase activity were assessed before culture and after 24 hr. Biopsies from untreated patients cultured with gluten showed low enzyme values and cuboidal epithelial cells before and after culture. Biopsies cultured in a gluten-free medium showed a threefold increase in enzyme values ($p<0.01$) and morphologic inprovement with change to columnar epithelial cells. Cultures with gluten plus cortisol showed rises in alkaline phosphatase and morphologic improvement indistinguishable from cultures without gluten. Cortisol and gluten had no effect on cultures from appropriate controls. It is concluded that cortisol prevents the harmful effects of gluten on biopsies from patients with gluten-sensitive enteropathy *in vitro*.

1962 SPECIFIC B-CELL ANTIGENS ASSOCIATED WITH GLUTEN-SENSITIVE ENTEROPATHY AND DERMATITIS HERPETIFORMIS. (Eng.) Mann, D. L.; Nelson, D. L.; Katz, S. I.; Abelson, L. D.; Strober, W. (Natl. Cancer Inst., Building 10, Bethesda, MD 20014). *Lancet* 1(7951):110-111; 1976.

B lymphocyte antigens were investigated in 16 patients with gluten-sensitive enteropathy (GSE), in 19 patients with dermatitis herpetiformis (DH), and in 37 normal individuals to determine a relation between their presence and diseases having HLA antigen associations. Antisera containing antibodies specific for B lymphocyte antigens were obtained from the wife of a patient with DH (antisera W-1) and from the mother of two children with GSE (B-1); other antisera with B lymphocyte reactivity were also used. None of the sera tested reacted with B lymphocytes from the normal individuals, whether they were histocompatability antigen HLA-B8-positive or not. Antiserum B-1 reacted with cells from 7 of 9 HLA-B8 positive, 6 of 7 HLA-B8-negative GSE patients, 12 of 15 HLA-B8-positive, and 3 of 4 HLA-B8-negative DH patients. Antiserum W-1 reacted with cells from 8 of 9 HLA-B8-positive, all of 7 HLA-B8-negative GSE patients, all 13 of HLA-B8-positive, and both of 2 HLA-B8-negative DH patients tested. The identification of this specific antigen provides further insight into the pathogenesis of GSE and DH and may form the basis of a diagnostic test for these diseases.

1963 ATOPIC DISORDERS AND ADULT COELIAC DISEASE.

(Eng.) Hodgson, H. J. F.; Davies, R. J.; Gent, A. E.; Hodson, M. E. (Royal Free Hosp., London NW3, England). *Lancet* 1(7951):115-117; 1976.

Thirty-three patients with adult celiac disease (ACD) and two with dermatitis herpetiformis and partial villous atrophy were studied to determine a relation with serum immunoglobulin levels or with a personal or family history of atopic disorders. A control group of 36 patients with ulcers or esophagitis was also studied. There were no overall differences in serum immunoglobulin concentrations between the two groups. Nineteen of the 35 patients with ACD had detectable auto-antibodies, compared with 2 controls ($p<0.001$). There was a personal history of atopic disorders (asthma, hay fever, or atopic eczema) in 10 of the 35 patients and in 2 of the 36 controls ($p<0.05$) and a family history of atopic disorders in 18 patients and in 8 controls ($p<0.025$). There were no differences in the frequencies of positive skin tests to 23 common allergens. The association of atopic disorders with patients and relatives of patients with ACD provides further evidence that underlying immunological abnormalities may be present in celiac disease.

1964 PATTERNS OF FOOD IRON ABSORPTION IN IRON-DEFICIENT WHITE AND INDIAN SUBJECTS AND IN VENESECTED HAEMOCHROMATOTIC PATIENTS.

(Eng.) Bezwoda, W. R.; Disler, P. B.; Lynch, S. R.; Charlton, R. W.; Torrance, J. D.; Derman, D.; Bothwell, T. H.; Walker, R. B.; Mayet, F. (Univ. Witwatersrand Medical Sch., Johannesburg, South Africa). *Br. J. Haematol.* 33(3):425-436; 1976.

The absorption of radioactive iron from a solution of ferrous ascorbate, and from a standard meal containing intrinsically labeled hemoglobin and wheat, was measured in 12 Indian housewives, 18 Caucasian hospital patients, and 12 subjects with idiopathic hemochromatosis. Eight of the latter had been treated by multiple venesections, so that their serum ferritin concentrations were below 25 μg/l. Since the serum ferritin concentrations of the housewives and the hospital patients were comparable, their body iron stores were considered to be depleted to a similar degree. There were no significant differences between the absorptions of ferrous ascorbate or of the heme iron in the standard meal by each group, but the housewives and the hospital patients absorbed significantly less of the nonheme food iron. The mean nonheme food iron absorptions were 36.4%, 5.8%, and 18.9% for the treated hemochromatotic subjects, the Indian housewives, and the hospital patients, resp. The ratios between the absorption of different types of dietary iron were calculated. The mean nonheme:heme food iron absorption ratio for the group of treated hemochromatotic subjects was 0.98, and for the housewives it was only 0.18. The hospital patients did not form a homogeneous population; the ratios of the 5 men and 3 of the women were greater than 1.0, whereas those of the remaining 10 women were less than 0.5. The results suggest that malabsorption of nonheme iron from a meal containing wheat, presumably due to a defect at the luminal level, may be an important factor in the pathogenesis of iron deficiency in some subjects. The abnormality appears to be particularly prevalent among Indian woman living in Durban, South Africa.

1965 ROLE OF FAT MALDIGESTION IN PATHOGENESIS OF STEATORRHEA IN ILEAL RESECTION. FAT DIGESTION AFTER TWO SEQUENTIAL TEST MEALS WITH AND WITHOUT CHOLESTYRAMINE.

(Eng.) Poley, J. R.; Hofmann, A. F. (Dept. Pediatrics, Univ. Ulm, Ulm, Germany). *Gastroenterology* 71(1):38-44; 1976.

To clarify the role of fat maldigestion in the pathogenesis of steatorrhea in patients with ileal resection, the total and aqueous phase concentrations of bile acid and fatty acid were characterized in eight such patients (five patients with small ileal resection, bile acid diarrhea, and steatorrhea less than 20 g/day; three patients with large ileal resection, fatty acid diarrhea, and steatorrhea greater than 20 g/day) and in four healthy control subjects after a morning and afternoon liquid test meal. The study was then repeated with the administration of 4 g of cholestyramine before each meal to induce fat maldigestion. After a conventional test meal, patients with large resections and severe steatorrhea had significantly lower aqueous phase concentrations of bile acids (and fatty acids) than patients with smaller resections or control subjects, explained, in part by intraluminal precipitation of about half of the bile acids during digestion. When cholestyramine was administered before the meal, aqueous phase bile acid concentrations decreased in all patients, including the normal control subjects; the degree of fat maldigestion induced in the patients with small resections (and the control subjects) became similar to that present after the conventional test meal in the patients with large resections. Because of the small increase in steatorrhea in the patients with small resections when cholestyramine was administered continuously, these data suggest that fat maldigestion does not induce severe fat malabsorption in patients with sufficient anatomical reserve. These patients can absorb fat efficiently by utilizing the distal small intestine. In patients with large ileal resections, severe steatorrhea is explained, in part, by the combination of fat maldigestion and decreased surface area. In addition, the steatorrhea occurring in patients with small resections and relatively normal fat digestion during two test meals may be explained by impaired fat digestion, which occurs during the final and often the largest meal of the day.

1966 RELATIONSHIP BETWEEN BILE ACID MALABSORPTION AND PANCREATIC INSUFFICIENCY IN CYSTIC FIBROSIS.

(Eng.) Weber, A. M.; Roy, C. C.; Chartrand, L.; Lepage, G.; Dufour, O. L.; Morin, C. L.; Lasalle, R. (Hopital Sainte-Justine, 3175 St. Catherine Road, Montreal H3T, 1C5, Quebec, Canada). *Gut* 17(4):295-299; 1976.

The increased bile acid (BA) loss observed in untreated children with pancreatic insufficiency secondary to cystic fibrosis (CF) was further investigated in 49 untreated children with CF and in 25 normal controls. The response of a small group of CF patients to various dietary and therapeutic interventions is also reported. BA loss (mg/m^2, 24 hr) in the stools of 43 patients with CF and pancreatic insufficiency was 751.1 ± 48.3, while that of 6 CF patients without clinical evidence of pancreatic disease (133.4 ± 15.9) did not differ from values in the 25 controls (109.8 ± 9.8). There was a good correlation between the degree of BA and fat sequestration. Concomitant changes in bile acid and fat loss were observed in one group of six patients who were studied on and off pancreatic enzymes as well as in a second group of seven children who were treated with pancreatic supplements and maintained on a normal diet followed by a low fat diet supplemented with medium chain triglycerides. Administration of sodium bicarbonate (15 g/1.73 m^3 x 24 hr) for 10 days led to a significant decrease in fat loss (15.8 ± 2.7 increased to 10.3 ± 1.9) without any simultaneous change in bile acid excretion (533.1 ± 58.3 increased to 500.4 ± 58.6). Qualitative bile acid patterns in eight controls, in four infants after an ileal resection, and in four patients with CF or with celiac disease showed that the percentage of primary BA followed closely the total amount excreted, except in situations where antibiotics were administered. The exact mechanism for the increased loss of BA in CF is unknown. It is found in all age groups and is related to the presence and degree of pancreatic insufficiency. The possibility that unhydrolyzed triglycerides may interfere with the intestinal absorption of bile acid needs further confirmation.

1967 VITAMIN B_{12} ABSORPTION--A STUDY OF INTRALUMINAL EVENTS IN CONTROL SUBJECTS AND PATIENTS WITH TROPICAL SPRUE. (Eng.) Kapadia, C. R.; Bhat, P.; Jacob, E.; Baker, S. J. (Christian Medical Coll. Hosp., Vellore, India). *Gut* 16(12): 988-993; 1975.

The intraluminal fate of p.o. administered radioactive vitamin B_{12} was studied in six control subjects with normal vitamin B_{12} absorption and in eight patients with vitamin B_{12} malabsorption due to tropical sprue. In control subjects, 1-21% of the dose was bound to sedimentable material and 37-75% was bound to immunoreactive intrinsic factor. In subjects with vitamin B_{12} malabsorption due to tropical sprue, the results were identical with the control subjects. Bacteriological studies showed a statistically significant correlation between both the number of flora in the jejunum and the number of bacteroides in both the jejunum and ileum and vitamin B_{12} malabsorption. Results indicate that in patients with tropical sprue who have normal intrinsic factor secretion, the vitamin B_{12} absorptive defect is not due to binding of the vitamin to bacteria or to alteration to the intrinsic factor vitamin B_{12} complex in the intestinal lumen. The lesion appears to be one of the mucosal cell receptors or of the cells themselves, possibly caused by bacterial toxins.

1968 THE VALUE OF ORGAN CULTURE IN THE STUDY OF THE PATHOGENESIS OF CELIAC DISEASE. (Fre.) Jos, J.; Rey, J. (INSERM, Hopital des Enfants-Malades, 149, rue de Sevres, 75730 Paris Cedex 15, France). *Arch. Fr. Mal. App. Dig.* 64(6): 461-464; 1975.

LARGE INTESTINE

1981 COLITIS ASSOCIATED WITH ORAL CLINDAMYCIN THERAPY. A CLINICAL STUDY OF 16 PATIENTS. (Eng.) Hoberman, L. J.; Eigenbrodt, E. H.; Kilman, W. J.; Hughes, L. R.; Norgaard, R. P.; Fordtran, J. S. (7711 Louis Pasteur Drive, Suite 409, San Antonio, TX 78229). *Am. J. Dig. Dis.* 21(1):1-17; 1976.

The clinical, radiologic, and histologic features of 16 patients hospitalized with clindamycin-associated colitis are presented. The findings were tabulated and compared to 33 cases reported in the literature. The majority of patients were females over 40 yr of age. The clinical presentation varied from mild persistent diarrhea to acute surgical abdomen. Proctoscopic examination revealed nonspecific colitis in nine and pseudomembranous colitis in seven cases. No specific radiologic or histologic findings for postantibiotic colitis were found. Therapy was nonspecific and varied according to the severity of the clinical course. Clinically, there appeared to be some benefit from systemic steroid therapy. Four patients died. During follow-up evaluation, none of the recovered patients had spontaneous relapses without medication. The pathogenic mechanism for postantibiotic colitis secondary to clindamycin remains unknown and does not appear dose-related. Clindamycin therapy should be limited to disorders with specific indications.

1982 COLLAGENOUS COLITIS WITH WATERY DIARRHOEA--A NEW ENTITY? (Eng.) Lindstrom, C. G. (Malmo General Hosp., Malmo, Sweden). *Pathol. Eur.* 11(1):87-89; 1976.

The case of a 48-yr-old woman with chronic watery diarrhea associated with an unusual rectal mucosa is described. Proctoscopy showed a macroscopically normal mucosa, but biopsy showed a thick subepithelial collagenous deposit. This deposit was of the same type as that described in the jejunal mucosa in collagenous sprue, and it seemed to be the cause of the diarrhea. It is proposed that the term "collagenous colitis or proctocolitis" be used to describe this disease.

1983 FAMILIAL "MINOR" ADENOMATOUS POLYPOSIS COLI ASSOCIATED WITH GASTRIC CARCINOMA--A HITHERTO UNDESCRIBED PHENOTYPE OF POLYPOSIS COLI? (Eng.) Ammann, R. W.; Deyhle, P.; Sulser, H. (Kantonsspital, CH-8091 Zurich, Switzerland). *Scand. J. Gastroenterol.* 11(3):233-240; 1976.

A clinical study of a family with a high incidence of death from gastric cancer in the second generation is presented. Endoscopic and/or surgical evaluation of the stomach, upper small intestine, and colon in 14 mainly asymptomatic members of the third and fourth generations revealed single or multiple (solitary) papillary adenomas in the colon or jejunum in 2 members each of the 2 generations. In addition, single or multiple hyperplastic polyps in the stomach or colon were found in five members, in four of them in association with papillary adenomas. The findings in the family are consistent with "minor" adenomatous polyposis coli associated with gastric carcinoma. Gastric carcinoma probably represents another phenotype among the variety of extracolonic and extra-alimentary neoplastic changes known to occur in association with familial polyposi coli. The relation of hyperplastic polyps to papillary adenoma in the colon and to gastric carcinoma, resp., is discussed.

1984 VOLVULUS OF THE RIGHT COLON: A REVIEW OF 30 CASES WITH SPECIAL REFERENCE TO LATE RESULTS OF VARIOUS SURGICAL PROCEDURES. (Eng.) Halvorsen, J. F.; Semb, B. H. K. (Haukeland sykehus, Univ. Bergen, Bergen, Norway). *Acta Chir. Scand.* 141(8):804-809; 1975.

Thirty patients who received different types of treatment for volvulus of the right colon during a

26-yr period are reviewed. Five patients died from unrelated causes during the follow-up period. Six patients did not receive surgery and had repeated attacks of transient bowel obstruction, not requiring hospitalization. Right hemicolectomy was performed in nine patients; one died of peritonitis postoperatively, and the remaining patients had no recurrence. Detorsion was performed in nine patients; of seven living patients, three are asymptomatic. Two patients treated with detorsion and cecostomy died during the early postoperative period. In four living patients in whom detorsion and cecopexy were performed, three remain asymptomatic, and no mortality was associated with this procedure.

LARGE INTESTINE

Ulcerative Colitis

2028 HISTOLOGICAL APPRAISAL OF ULCERATIVE COLITIS IN FIBREOPTIC COLONOSCOPE BIOPSY SPECIMENS. (Eng.) Lee, S. K.; Fung, W. P. (Dept. Pathology, Univ. Singapore, Outram Road, Singapore 3). *Med. J. Aust.* 63(1/2):8-11; 1976.

On the basis of 157 colonoscopic biopsies taken from 38 patients with endoscopic appearances of ulcerative colitis, the histological changes of the disease are described, and a histological classification is proposed. The classification is as follows: (a) active chronic phase without ulceration, (b) active chronic phase with ulceration, (c) quiescent chronic phase, (d) healed chronic phase, and (e) precancerous phase. Three degrees of severity (mild, moderate, and severe) are recognized for each phase. The classification is sufficiently flexible to allow recognition of the various stages of the disease process. It is suggested that it be adopted for the clinical management of patients and for future investigations into the etiology and other aspects of ulcerative colitis.

2029 ENTEROCHROMAFFIN CELLS AND MACROPHAGES IN ULCERATIVE COLITIS AND IRRITABLE COLON. (Eng.) Ahonen, A.; Kyosola, K.; Penttila, O. (Dept. Anatomy, Univ. Helsinki, Siltavuorenpenger 20, SF-00170 Helsinki 17, Finland). *Ann. Clin. Res.* 8(1): 1-7; 1976.

The type and the number of fluorescent cells were studied in rectal biopsies from six patients with ulcerative colitis, six patients with irritable colon, and nine controls. The specimens were studied by formaldehyde-induced fluorescence after freeze-drying and Epon embedding. The mean number of enterochromaffin cells per crypt was increased over that of the controls in five patients with irritable colon, whereas the patients with ulcerative colitis had fewer enterochromaffin cells than did the controls. There were autofluorescent macrophages in almost every biopsy specimen, and various types of autofluorescent granules were observed in the cytoplasm. The results confirm previous studies that indicate that the number of enterochromaffin cells is decreased in ulcerative colitis.

2030 EVIDENCE OF AN AGENT TRANSMISSIBLE FROM ULCERATIVE COLITIS TISSUE. (Eng.) Cave, D. R.; Mitchell, D. N.; Brooke, B. N. (St. George's Hosp., London, England). *Lancet* 1(7973):1311-1314; 1976.

Five New Zealand white rabbits were injected intracolonically with homogenates (100 μm) of ulcerative colitis tissue to study the possibility of a transmissible agent in this tissue. Histological changes similar to those seen in the human donors were present in the mucosa and submucosa of the large in-

LIBRARY U. S.

testine of 4 of these rabbits, 3-12 months later. Similar changes were seen in the large intestine of 3 of 4 rabbits, 6-13 months after i.v. or intracolonic inoculation of homogenates of rabbit mesenteric lymph nodes after passage of human ulcerative colitis tissue (100 μm or 0·2 μm). Three of 30 A_2G strain mice, which were injected with similar tissue homogenates (100 μm or 0·2 μm) from patients with ulcerative colitis, into the footpad or i.p., had granulomatous changes in footpad, bowel, liver, and/or spleen, 3-22 months later. Such changes did not develop in rabbits or mice inoculated with tissue from normal controls. The results suggest that a transmissible factor is involved in the etiology of ulcerative colitis.

2031 IMPLICATIONS OF PRECANCEROUS RECTAL BIOPSY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE. (Eng.) Gewertz, B. L.; Dent, T. L.; Appelman, H. D. (Univ. Michigan Medical Center, Ann Arbor, MI 48104). *Arch. Surg.* 111(4):326-329; 1976.

Retrospective studies were undertaken in 65 patients with an initial diagnosis of ulcerative colitis who underwent total proctocolectomy between 1955 and 1973. Rectal mucosa in each patient was examined microscopically for the presence or absence of "precancerous" alterations. Histologic examination was made without knowledge of concomitant colon carcinoma or the patients' clinical courses. Three of 10 patients with precancerous rectal mucosa had invasive colon carcinoma, while none of the 55 patients without such changes had colon cancer. The duration of disease was significantly greater in those patients with rectal precancer ($p<0.05$). Reexamination changed the pathologic diagnosis in 15 patients from ulcerative colitis to granulomatous or "mixed" colitis. Two of three invasive cancers occurred in the reclassified group. The results indicate that careful histologic evaluation of rectal biopsy specimens from individuals with inflammatory bowel disease may better define that population of patients with an increased risk of colonic carcinoma.

2041 MORPHOLOGICAL LESIONS ASSOCIATED WITH HUMAN PRIMARY INVASIVE NONENDOCRINE PANCREAS CANCER. (Eng.) Cubilla, A. L.; Fitzgerald, P. J. (Memorial Hosp., 1275 York Ave., New York, NY 10021). *Cancer Res.* 36(7):2690-2698; 1976.

Pancreatic duct epithelium was studied in 227 cases of human pancreatic cancer (100 pancreatectomy specimens and 127 autopsies) and in 100 age- and sex-matched control nonpancreatic cancer cases, to determine the prevalence of the lesions and their possible precursor relation to invasive pancreas cancer. The prevalence of squamous metaplasia, pyloric gland metaplasia, mucous hypertrophy, and focal epithelial hyperplasia was not significantly different in the two groups. Ductal papillary hyperplasia was three times more prevalent in patients with pancreas cancer than in controls. Marked atypia occurred in 20% and carcinoma *in situ* in 18% of the pancreas cancer cases, but neither change was seen in the control cases. It is possible that focal epithelial hyperplasia was a precursor change but that it was overgrown by the cancer. Papillary hyperplasia could not be properly evaluated as a precursor lesion because of duct obstruction, but practically all cases of marked atypia and carcinoma *in situ* occurred in papillary lesions. Marked atypia and carcinoma *in situ*, by analogy to other cancers, appear to be precursor lesions, and their presence in association with invasive cancer supports the possibility that there is a significant, recognizable *in situ* phase of the disease prior to the occurrence of invasive cancer.

2042 DUODENAL JUICE EXAMINATION AND SE-75-METHIONINE ELIMINATION IN PANCREATIC DAMAGE (2°). (Eng.) Scortecci, V.; Poma, S.; Micucci, E. (Istituto di Patologia Chirurgica II dell'Universita degli Studi di Milano, Milan, Italy). *Chir. Gastroenterol.* 9(1):101-103; 1975.

The elimination of ^{75}Se-methionine as a tracer of pancreatic function was studied in 17 patients, using double hormonal stimulation (secretin and pancreozymin). The cases included acute, chronic, recurrent, and sclerosing pancreatitis, chronic gastritis, cholelithiasis, bile duct carcinoma, cirrhosis, duodenal ulcer, appendicitis, bile duct lithiasis, papillary sclerosis, and chronic pancreatitis bile duct stone. Tracer excretion appeared early and peaked at 10 min; the tracer appeared very rapidly (1-2 min) in the pancreatic juice of patients with chronic pancreatitis. It is concluded that the study of ^{75}Se-methionine excretion in duodenal juice is a reliable means of determining the presence of pancreatic lesion even in the inital stage of the disease.

2043 SALIVARY AMYLASE IN DUODENAL ASPIRATES. (Eng.) Skude, G.; Ihse, I. (Malmo General Hosp., S-214 01 Malmo, Sweden). *Scand. J. Gastroenterol.* 11(1):17-20; 1976.

The significance of the contamination of pancreatic amylase by salivary amylase, occuring during the collection of duodenal aspirates for pancreatic function tests, was investigated. Salivary and pancreatic isoamylases in duodenal aspirates obtained from 47 pancreatic function tests in 45 subjects, after test meal stimulation, were separated by agarose gel electrophoresis. Salivary amylase was found to be a constituent of the duodenal aspirates in over 75% of the tests. The mean relative contribution of salivary amylase to the total amylase activity of the aspirates varied from about 15% in 20 normal subjects to about 40% in patients with chronic pancreatitis and pancreatic carcinoma. The amount of salivary amylase varied widely not only between the individuals but also within the samples of the same test series. Specific determination of the pancreatic isoamylases instead of determination of the total amylase increased the discrimination between normals and patients with pancreatic dysfunction. This study indicates that amylase should be fractionated quantitatively into pancreatic and salivary components or that other enzymes should be used to reflect pancreatic function.

2044 DIETARY EFFECTS IN THE EARLY RECOVERY PHASE OF KWASHIORKOR. (Eng.) Persson, B.; Habte, D.; Sterky, G. (St. Goran's Children's Hosp., Box 12500, S-11281 Stockholm, Sweden). *Acta Paediatr. Scand.* 65(3):329-336; 1976.

The effect on lipid metabolism of 2 isocaloric diets, synthetic monomolecular (Vivonex) and standard (Casilan), was studied in 21 children with kwashiorkor during the first weeks of rehabilitation. Before treatment, mean fasting values of all biochemical parameters were within normal ranges except for moderately elevated triglycerides (0.39-3.49 mmol/l) and low insulin. Free fatty acid (FFA) levels correlated with glycerol, D-β-hydroxybutyrate, and triglyceride values. During treatment, insulin, glucose, and glycerol remained essentially unchanged and were similar in both dietary groups. In the Vivonex group only, there was an initial marked, parallel fall of FFA and D-β-hydroxybutyrate, suggesting greater availability of carbohydrate and enhanced glucose utilization. This pattern of response occurred without comparable inhibition of lipolysis. Triglycerides, like serum albumin, increased faster in the Casilan group. The highest mean triglyceride value was reached by day 8 in the Casilan group and by day 15 in the Vivonex group. Ten min following heparin injection, triglycerides declined, and FFA and glycerol increased, indicating release of *in vivo* active lipase. Lipoprotein lipase (LPL) activity, assayed *in vitro* was similar and unaffected by 2 weeks of dietary treatment in both groups. LPL activity was inversely correlated to triglycerides, providing another possible explanation for the wide variations seen in circulatory triglycerides.

Pancreatitis

2056 PERCUTANEOUS PUNCTURE OF PANCREATIC CYSTS GUIDED BY ULTRASOUND. (Eng.) Hancke, S.; Pedersen, J. G. (Gentofte Hosp., Hellerup, Denmark). *Surg. Gynecol. Obstet.* 142(4):551-552; 1976.

A method for percutaneous puncture of pancreatic cysts, using ultrasound, is presented. Fifteen pancreatic cysts in 14 patients were successfully punctured percutaneously under the guidance of ultrasonic B scanning. The cysts were 3-20 cm in diameter. Only one patient had any complications; a 200-ml hematoma was discovered between the liver and stomach, during laparotomy, 3 months after the procedure. Ultrasonically guided percutaneous puncture of pancreatic cysts appears to be a simple procedure for verifying ultrasonic diagnosis, for decompression in the case of threatening rupture, and for allowing time for maturation of the cyst membrane before surgical intervention. The fact that two patients were without a recurrence after 12 months may indicate the possibility of definitive therapy using this technique.

LIVER AND BILIARY TRACT

2069 SAMPLING INTESTINAL CONTENT WITH A SEQUESTERING CAPSULE: A NONINVASIVE TECHNIQUE FOR DETERMINING BILE ACID KINETICS IN MAN. (Eng.) Hoffman, N. E.; LaRusso, N. F.; Hofmann, A. F. (Dept. Medicine, Univ. Melbourne, Melbourne, Australia). *Mayo Clin. Proc.* 51(3):171-175; 1976.

A noninvasive technique for determining bile acid kinetics by isotope dilution in man is described. It features the i.v. injection of a radiolabeled bile acid, together with daily p.o. administration of capsules of dialysis membrane containing cholestyramine and colored beads for dating. The cholestyramine traps conjugated bile acids during transit of the small intestine. Capsules are recovered from stool by a sieving method; sequestered bile acid is eluted, conjugated bile acids are isolated chromatographically, and their specific activity is determined. The precision and validity of this sequestering capsule technique were assessed by comparing the specific activity decay curve of chenodeoxycholyl conjugates obtained from capsule samples with that obtained from duodenal samples in seven healthy volunteers in whom the bile acid pool was labeled with $[^{14}C]$chenodeoxycholic acid. Estimates of pool size by the two methods correlated well ($r=0.98$), as did the daily fractional turnover rate ($r=0.96$). The mean percentage differences for the kinetic parameters of pool size (8.3 ± 13.6), fractional turnover rate (-15.2 ± 11.5), and synthesis rate (-4.3 ± 11.4) were small, indicating that the noninvasive method is valid. However, agreement between simultaneously administered capsules was only fair, especially when the amount of bile acid trapped was small. It is suggested that the precision of the capsule technique may be less than that of the con-

LIBRARY U. OF F. [illegible]

ventional sampling technique; the latter probably obtains a more valid sample of the bile acid pool.

2070 EFFECT OF ASPIRIN ON LIVER TESTS IN PATIENTS WITH RA OR SLE AND IN NORMAL VOLUNTEERS.

(Eng.) Seaman, W. E.; Plotz, P. H. (Massachusetts General Hosp., Boston, MA). *Arthritis Rheum.* 19(2):155-160; 1976.

The effects of aspirin on the liver were evaluated in a prospective study of 20 patients with rheumatoid arthritis (RA), 16 patients with systemic lupus erythematosus (SLE), and 3 normal volunteers. Effects were also assessed in a retrospective study of 80 patients with SLE. The subjects were given 50 mg/kg/day of aspirin (4 times daily); this dose was raised by 640 mg every other day until a morning serum salicylate level of 25-30 mg/100 ml was achieved. The dosage was then adjusted to this level for 2 weeks. Four RA patients, seven SLE patients, and one normal subject developed elevated transaminases. This occurred at or near the end of the 2-week study period in the RA patients. Elevated transaminases were most frequent and of most rapid onset in patients with clinically active SLE. Elevations in blood urea nitrogen occurred in four patients with SLE. In the retrospective study, undertaken over a 2.5-yr period, 19 of the 80 patients showed elevated transaminase levels. The aspirin dosage associated with these abnormalities ranged from 640 mg/day to 5,760 mg/day. It appears that salicylates are mildly hepatotoxic in some persons, and this may be augmented by SLE and perhaps by other illnesses.

2071 ALTERATIONS IN TISSUE FERRITINS IN IRON STORAGE DISORDERS.

(Eng.) Powell, L. W.; McKeering, L. V.; Halliday, J. W. (Royal Brisbane Hosp., Brisbane, Australia). *Gut* 16(11):909-912; 1975.

Purified tissue ferritins isolated from two Bantu subjects with gross hemosiderosis, from a patient with idiopathic hemochromatosis (IHC) treated by phlebotomy, from a normal subject, and from male Sprague-Dawley rats with experimental iron overload were analyzed by polyacrylamide gel electrophoresis to determine the significance of the abnormality previously demonstrated in tissue isoferritins in patients with IHC. The isoferritin profile of the tissues from the Bantu subjects and the iron-loaded rats showed an abnormality similar to that previously found in patients with untreated IHC: an abnormally uniform distribution of iron-containing isoferritins with an increase in the more basic isoferritins and an apparent absence of the more acidic ones. In contrast, tissues from the patient with treated IHC, who was iron depleted at the time of death, showed the normal organ-specific isoferritin distribution. These findings suggest that the abnormal distribution of tissue isoferritins in IHC is an acquired phenomenon and is not likely to be related to an underlying genetic defect in ferritin or iron metabolism.

2072 ASSOCIATION OF HLA-A3 AND HLA-B14 ANTIGENS WITH IDIOPATHIC HAEMOCHROMATOSIS.

(Eng.) Simon, M.; Bourel, M.; Fauchet, R.; Genetet, B. (Hopital Pontchaillou, 35043 Rennes Cedex, France). *Gut* 17(5):332-334; 1976.

The frequency of HLA-A3 and HLA-B14 antigens was studied in 51 patients with idiopathic hemochromatosis and it was compared with the frequency in 204 normal blood donors. HLA-A3 and HLA-B14 antigens occurred more frequently in the patients with hemochromatosis than in the controls, 78.4% versus 27.0% and 25.5% versus 3.4%, resp. This finding strongly supports the suggestion that idiopathic hemochromatosis is a genetic disease and suggests that the gene(s) responsible for the disease may be linked to the histocompatibility genes.

2073 CARCINOEMBRYONIC ANTIGEN: EVIDENCE FOR MULTIPLE ANTIGENIC DETERMINANTS AND ISOANTIGENS.

(Eng.) Vrba, R.; Alpert, E.; Isselbacher, K. J. (Harvard Medical Sch., Boston, MA 02114). *Proc. Natl. Acad. Sci. U.S.A.* 72(11):4602-4606; 1975.

Carcinoembryonic antigen (CEA) preparations from various sources were compared by radioimmunoassay. CEA-Roche standard differed significantly from the other three CEA standards tested (CEA-Montreal, CEA-City of Hope, and CEA-British). The serum CEA from a patient with colonic cancer and a serum CEA concentration of over 26,000 ng/ml were antigenicall different from currently available CEA standards as well as from the CEA obtained from the patient's own liver metastases. These antigenic differences were reflected in radioimmunoassay inhibition curves that were different and that were not affected by perchloric acid extraction of CEA. Because of the antigenic variation in the serum CEA, markedly different CEA concentrations (varying by three orders of magnitude) were measurable by two different antisera (Roche and Montreal). All the various CEA standards and samples cochromatographed on columns of Sepharose-6B, despite the large antigenic variation. It is postulated that CEA consists of a family of "isoantigens" with multiple antigenic determinants. Because a different serum CEA isoantigen was isolated, the authors believe that results of radioimmunoassays currently used for CEA measurement may not represent absolute concentrations of serum "CEA," but may reflect the binding affinity of different isoantigens to a particular polyvalent CEA antiserum.

2074 LAPAROSCOPY IN LIVER DISEASE.

(Eng.) Balfour, T. W. (General and City Hosps., Nottingham, U.K.). *Lancet* 1(7960):612-613; 1976.

The use of laparoscopy in the diagnosis of liver disease was evaluated. Results indicate that it was technically successful in 73 of 75 patients in whom liver disease was suspected but not accurately diagnosed after medical investigation. In 46 patients, the final histological diagnosis was either diffuse parenchymatous disease (cirrhosis/hepatitis) or metastatic malignant disease; 2 patients had a curable medical disease (tuberculous ascites), and 6 had a curable surgical disease (5 with gallstones and 1 with an ectopic adrenal tumor). There were no deaths and no serious complications. In conjunction with increasingly accurate noninvasive techniques for localizing lesions in the liver, laparoscopy, with directed biopsy, should help to provide correspondingly accurate histological confirmation.

2075 LYMPHOCYTE TRANSFORMATION TEST WITH LIVER-SPECIFIC PROTEIN AND PHYTOHAEMAGGLUTININ IN PATIENTS WITH LIVER DISEASE. (Eng.) Thestrup-Pedersen, K.; Ladefoged, K.; Andersen, P. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Clin. Exp. Immunol.* 24(1):1-8; 1976.

Lymphocytes from 34 untreated patients with various liver diseases were stimulated in a lymphocyte transformation test with liver-specific protein (LSP). Eight of 10 patients with chronic active or persistent hepatitis, 2 of 5 patients with nonalcoholic cirrhosis, and 6 of 19 patients with acute hepatitis showed a positive *in vitro* reactivity to LSP. In a control group of 12 persons without liver disease, 11 gave a negative response to LSP stimulation, and 1 person showed a positive response. Among 14 patients with chronic hepatitis or nonalcoholic cirrhosis treated with prednisone at the time of the investigation, only 1 showed reactivity to LSP stimulation. Three patients in this group had a positive reaction before prednisone was given. There was no statistically significant correlation between the reactivity to LSP stimulation and the presence or absence of hepatitis-associated antigen (HBAg) in serum, or with the biochemical liver parameters. The response to *in vitro* stimulation with phytohemagglutinin was found to be significantly lower as compared with the control group, with 11 patients with alcoholic liver disease, and with the patients with acute hepatitis who had HBAg in serum. This decrease in reactivity could not be ascribed to immunosuppressive factors in the patients' sera.

2076 LIVER SCAN IN BUDD-CHIARI SYNDROME. (Eng.) Meindok, H.; Langer, B. (Toronto Western Medical Building, 25 Leonard Ave., Toronto, Ontario M5T 2R2, Canada). *J. Nucl. Med.* 17(5):365-368; 1976.

The value of hepatic scintigraphy in the diagnosis and follow-up of the Budd-Chiari syndrome (occlusion of hepatic veins) was assessed in 17 liver scans of 7 patients with confirmed Budd-Chiari syndrome. In five patients whose three main hepatic veins were occluded, liver scans (with ^{198}Au-colloid or ^{99m}Tc-sulfur colloid) showed hepatomegaly, markedly diminished uptake over the left and right hepatic lobes involving the right more than the left, and a persistent midline region of normal or increased uptake. The latter effect is probably caused by uptake in segments surrounding the inferior vena cava that have direct venous drainage. In the two patients with incomplete occlusion, there was absent or diminished uptake in the scans over the segments with occluded veins. Liver scans were useful in the follow-up of one patient following portocaval shunting. Good correlation existed between selective venography and liver scan findings. It is concluded that liver scan appearance is characteristic enough to warrant consideration of the Budd-Chiari syndrome as the first diagnosis.

2077 A NEW APPROACH TO EVALUATING HEPATIC BLOOD FLOW IN THE PRESENCE OF INTRAHEPATIC PORTAL SYSTEMIC SHUNTING. (Eng.) Gross, G.; Goldberg, H. I.; Shames, D. M. (Univ. California Sch. Medicine, San Francisco, CA 94143). *Invest. Radiol.* 11(2):146-149; 1976.

A new radioisotopic technique for determining the percent of portal venous flow shunted around the hepatic sinusoidal bed was tested in two newborn lambs (which have a temporary, naturally occurring shunt) and in four dogs. The method involved the injection of 20- to 50-µ particles of technetium-99m (^{99m}Tc) microaggregates of albumin (MAA) into the portal vein; these particles are too large to pass through the hepatic sinusoids and would pass through the collaterals found in patients with portal hypertension. Pulmonary isotope activity was measured in the upper portion of the right lung. This area was also monitored following an injection of ^{99m}Tc MAA in a peripheral vein, representing the equivalent activity of a 100% portal systemic shunt. The portal vein was reached via the umbilical vein or the pancreatic vein in the lamb and the dog, resp. In one lamb, the 46% portal systemic flow that was shunted 12 hr after birth decreased to 9% by the third day. In the other lamb, a 3% shunt at 72 hr after birth was associated with a very small ductus venosus. Five days after birth, when the ductus venosus closed, an apparent 1% shunt was present. There was an apparent 1.5-3.9% shunted portal systemic flow in the dogs. This was attributed to the breakdown of ^{99m}Tc, allowing particles to pass through the sinusoids; in one dog, stable ^{95}Nb microspheres, instead of MAA, showed the flow to be reduced to 0.2%. This technique may be useful in determining the type of surgery necessary for bleeding varices, in patients with intrahepatic shunting associated with cirrhosis.

2078 DIAGNOSIS OF HEPATIC HEMANGIOMA USING MULTIPLE-RADIONUCLIDE AND ULTRASOUND TECHNIQUES. (Eng.) Taylor, R. D.; Anderson, P. M.; Winston, M. A.; Blahd, W. H. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *J. Nucl. Med.* 17(5):362-364; 1976.

Two cases of hepatic hemangioma, in which multiple-radionuclide and ultrasound techniques were combined in the diagnostic process, are reported. In both patients, 32- and 47-yr-old men, radiocolloid liver

LIBRARY U. S.

scans revealed a large focal defect in the liver, and ultrasound studies demonstrated that the defect was solid. A ^{67}Ga scan in the second patient revealed that images obtained within 6 hr of ^{67}Ga administration could be used to evaluate the blood pool of the lesion. Dynamic perfusion studies with ^{99m}Tc-sulfur colloid in both patients showed no increased perfusion in the region of the lesions, but blood pool scans performed with ^{111}InCl revealed increased uptake in the lesion. Hepatic contrast angiograms gave findings consistent with hepatic hemangioma in both patients. These cases show that noninvasive radionuclide and ultrasound techniques are useful in determining vascularity, blood pool, and, frequently, the pathologic nature of focal hepatic lesions, often obviating the need for invasive contrast angiography. Blood pool imaging proved to be the most definitive diagnostic procedure for the identification of hepatic hemangiomas.

2079 FINE-NEEDLE BIOPSY OF THE LIVER COMPLICATED WITH BILE PERITONITIS. (Eng.) Schulz, T. B. (Aust-Agder Sentralsykehus, Arendal, Norway). *Acta Med. Scand.* 199(1):141-142; 1976.

The case of a previously healthy man who developed bile peritonitis as a complication of fine-needle aspiration biopsy to screen for primary hemochromatosis is presented. During aspiration, bile appeared in the syringe, and laparotomy was necessary 24 hr later. About 1.5 l bile was found in the abdominal cavity; no lesions of the biliary system were seen. Treated with drainage, the further course was uncomplicated. It is suggested that the appearance of bile peritonitis following fine needle biopsy is a rare condition, but that it should be kept in mind when electing this method.

2080 NON-INVASIVE QUANTITATION OF CORNEAL COPPER IN HEPATOLENTICULAR DEGENERATION (WILSON'S DISEASE). (Eng.) Belkin, M.; Chajek, T.; Zeimer, R.; Friedman, G.; Melamed, E. (Hadassah Univ. Hosp., Jerusalem, Israel). *Lancet* 1(7957): 391-392; 1976.

The corneal copper content was measured in seven patients with Wilson's disease and in two normal subjects, by x-ray excitation spectrometry. Patients who were treated irregularly or not treated at all showed a high corneal copper content. Those who were adequately treated (penicillamine, 1-4 yr) had low levels, comparable to the controls. In one case, the corneal copper content declined by 45%, after a course of dimercaprol. The corneal copper measured showed no correlation with the slit-lamp appearance of the Kayser-Fleischer ring. It is suggested that non-invasive x-ray excitation spectrometry can provide a fast and reliable method for the early diagnosis of Wilson's disease and for the objective evaluation of treatment methods.

2081 USE OF CLINDAMYCIN IN PATIENTS WITH LIVER DISEASE. (Eng.) Hinthorn, D. R.; Baker, L. H.; Romig, D. A.; Hassanein, K.; Liu, C. (Univ. Kansas Medical Center, Kansas City, KS 66103). *Antimicrob. Agents Chemother.* 9(3):498-501; 1976.

Clindamycin (300 mg, i.v.) was administered at 12-hr intervals for 2 days to seven patients with acute hepatitis, six patients with chronic hepatitis, nine patients with cirrhosis, and eight controls to determine whether the drug exacerbates pre-existing hepat dysfunction or whether drug excretion is delayed in patients with liver disease, as compared with controls. Exacerbation of hepatotoxicity was not found in this study. There was a small, but significant, delay in drug elimination between cirrhotics and controls, even after the first dose of clindamycin ($p<0.05$); however, half-lives in all categories were normal. It is concluded that clindamycin can be used in patients with acute or chronic hepatitis, or cirrhosis, but that periodic observations of drug activity levels and liver enzyme determinations are necessary.

2082 COMBINATION CHEMOTHERAPY WITH 5-FLUOROURACIL (NSC-19893), METHOTREXATE (NSC-740), PREDNISOLONE (NSC-9900) (FAP PROTOCOL) FOR HEPATOMA. (Eng.) Umsawasdi, T.; Chainuvati, T.; Hitannant, S.; Nilprabhassorn, P.; Viranuvatti, V. (Siriraj Hosp., Bangkok 7, Thailand). *Cancer Chemother. Rep.* 59(6):1167-1169; 1975.

A new protocol consisting of 5-fluorouracil (300 mg/m^2/day, days 1, 8, 15, 22, 29, and 36 of treatment), methotrexate (7 mg/m^2/day, days 1-5, 22-26), and prednisolone (25 mg qid, days 1-5, 22-26) was used in the treatment of 11 patients with hepatocellular carcinoma. One patient responded with complete disappearance of all tumor masses for 207 days. A 50% or greater reduction of all lesions, without evidence of new lesions, and a 30-49% reduction were seen in one and four patients, resp. Complications included nausea, vomiting, stomatitis, alopecia, intermittent diarrhea, thrombocytopenia, hemoperitoneum, and granulocytopenia. The results suggest that this regimen is more effective in patients with normal or nearly normal liver function tests and in those without pulmonary metastases.

2083 EFFECTS OF HYPERTHERMIA THERAPY ON THE LIVER. II. MORPHOLOGICAL OBSERVATIONS. (Eng.) Wills, E. J.; Findlay, J. M.; McManus, J. P. A. (Clinical Res. Center, Harrow, England). *J. Clin Pathol.* 29(1):1-10; 1976.

Light and electron microscopy were used to study liver biopsy specimens obtained from three patients during exogenous hyperthermia treatment of advanced malignant disease. In two patients, the parenchymal cells showed either slight swelling or nuclear alterations by light microscopy; large numbers of autophagic vacuoles, dilatation of Golgi elements and endoplasmic reticulum, and large cytoplasmic vacuoles were observed at the fine structural level. Similar changes, but in much more severe form, together with parenchymal cell necrosis and cholestasis, were seen in the liver of the third patient, who developed jaundice 24 hr after hyperthermia. The degree of liver cell damage in this case was thought to be related to the duration of hyperthermia and to the maximum temperature attained in this patient. However, the findings in the other two cases indicate that transient liver damage probably occurs in all patients who are subjected to hyperthermia.

2084 LIVER-CELL ADENOMAS ASSOCIATED WITH USE OF ORAL CONTRACEPTIVES. (Eng.) Edmondson, H. A.; Henderson, B.; Benton, B. (Univ. Southern California Sch. Medicine, 2025 Zonal Ave., Los Angeles, CA 90033). *N. Engl. J. Med.* 294(9):470-472; 1976.

Possible etiologic factors, including the use of oral contraceptives, were studied in 36 women with liver-cell adenomas. These cases were compared with 34 age-matched controls. Twenty-nine patients and 24 controls had used oral contraceptives. There was a significant difference between cases and controls in mean number of months of contraceptive use--73.4 as compared to 36.2 ($p<0.001$). The women with adenomas took mestranol-containing pills, as opposed to compounds containing ethinyl estradiol, in more cases than did the controls ($p<0.0001$). In 10 cases, the adenoma bled into its substance and ruptured into the abdominal cavity. Eight of these women had a history of use of oral contraceptives, and a history was not available in the other two. The tumors were encapsulated lesions 6-30 cm in diameter, and both infarction and hemorrhage were present in 29 adenomas. The authors conclude that long-term use of oral contraceptives, especially those containing a high total dose of steroids or mestranol, should be balanced against risks of side effects. If a choice is available, contraceptives containing a low dose of estrogen and progesterone and preferably, ethinyl estradiol as the synthetic estrogen should be selected.

2085 PRECURSOR LESIONS FOR LIVER CANCER IN HUMANS. (Eng.) Anthony, P. P. (Middlesex Hosp. Medical Sch., London W.1, England). *Cancer Res.* 36(7):2579-2583; 1976.

The known risk factors leading to liver cell carcinoma in humans are reviewed. Cirrhosis is the most important precursor lesion; both the causative agent and the time of duration of the cirrhotic process are relevant to the magnitude of this risk. According to present knowledge, α_1-antitrypsin deficiency, alcoholism, naturally occurring carcinogens, drugs, and the hepatitis B virus seem to carry the greatest risk of cancer developing in a cirrhotic patient. Cirrhosis, however, is not an essential prerequisite, and some or possibly all of these agents can also induce cancer without cirrhosis. Bile duct carcinoma commonly follows infestation with liver flukes. Cirrhosis is usually absent but duct epithelial hyperplasia is present prior to the development of cancer. Many cellular changes have been observed in patients and among populations considered to be at risk from liver cancer. Of these, liver cell dysplasia is the most striking and studies of its prevalence, natural history, and association with cirrhosis suggest that it is a precancerous change.

2086 CHANGES IN LACTIC DEHYDROGENASE ISOENZYMES AFTER HEPATIC ARTERY LIGATION IN PATIENTS WITH HEPATIC CARCINOMA. (Eng.) Nagasue, N. (Kyushu Univ. Sch. Medicine, 3-1-1 Maidashi, Higashi-ku, Fukuoka, 812 Japan). *Gastroenterol. Jpn.* 10(2):150-156; 1975.

Serum activities of LDH isoenzymes as well as total LDH, SGOT, and SGPT were determined after hepatic artery ligation in five patients with primary or metastatic liver cancer. Transaminases and total LDH activities were raised after the operation, showing peaks on the first or third postoperative days. LDH$_2$, LDH$_3$, and LDH$_5$ increased substantially during the first three postoperative days. These changes became nearly normalized within 2 weeks after hepatic artery ligation. As control, the same enzymatic activities were measured in eight patients after laparotomies, but no significant abnormalities were observed postoperatively. Thus, liberation of cathodic and also anodic migrating LDH isoenzymes seems to occur after acute liver damage induced by hepatic artery ligation. It is also suggested that serial determination of LDH isoenzymes as well as total activity can be valuable for evaluating the antitumor effect of hepatic artery ligation.

2087 FOCAL NODULAR HYPERPLASIA OF THE LIVER: FIVE CASES. (Eng.) Sorensen, T. I. A.; Almersjo, O. (Gentofte Hosp., DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 11(1):97-101; 1976.

Five cases of benign focal nodular hyperplasia are presented. The patients ranged in age from 25 to 54 yr. One patient exhibited no symptoms other than a liver mass, while the other patients demonstrated pain, anorexia, and minor weight loss. Extrahepatic compression of the portal vein due to the location of the tumor in the omental sac was seen in one patient, and other complications were rare. Biopsy with frozen section excluded malignancy, and yielded the diagnosis from the cirrhosis-like appearance of the tumor. The tumor was excised in four cases and left in place in one, and no evidence of recurrence or metastases was found for 7-59 months. It is concluded that patients with complications or significant symptoms should be treated by removal of the tumor by local resection, or if necessary, by larger hepatic resection. In asymptomatic patients or in those with vague complaints, the tumor may be left in place with minimal risk.

2088 SURGICAL TREATMENT OF HEPATIC METASTASES FROM COLORECTAL CANCERS. (Eng.) Wilson, S. M.; Adson, M. A. (Mayo Graduate Sch. Medicine, Univ. Minnesota, Rochester, MN). *Arch. Surg.* 111(4): 330-334; 1976.

Sixty patients who had resection of hepatic metastases for colorectal cancer were followed up for 2-23 yr. Multiple lesions were removed from 20 patients and solitary lesions were excised from the other 40 patients. Only one patient died during hospital convalescence. No patient who had excised multiple lesions lived for 5 yr. In contrast, 15 of the 36 patients who had resection of apparent solitary lesions lived for 5 yr or more, and 8 patients were alive without evidence of recurrence 10 yr or more after operation. These favorable results of surgical treatment were analyzed in relation to results in 60 patients whose biopsy specimens showed lesions of comparable size and number, which were not removed at the time of colonic resection. No patient in this control group lived for 5 yr. Aggressive surgical treatment of apparent solitary hepatic metastatic lesions from colorectal cancer seems to be justified by the survival rate of surgically treated patients.

2089 PROGRESSIVE INTRAHEPATIC CHOLESTASIS (BYLER'S DISEASE): CASE REPORT. (Eng.) De Vos, R.; De Wolf-Peeters, C.; Desmet, V.; Eggermont, E.; Van Acker, K. (Akademisch Ziekenhuis Sint Rafael, Minderbroedersstraat 12, B 3000 Leuven, Belgium). *Gut* 16(12):943-950; 1975.

The clinical and microscopic findings in a 7-month-old girl with intrahepatic cholestasis (Byler's disease) are presented. The patient presented with pruritus, loose stools, and severe rickets. Hepatic excretion of bile acids, sulfobromophtalein, I^{131} Rose Bengal, and adipiodon-methyl-glucaminate were impaired. There was a pronounced block of bile salt excretion into the intestinal lumen. Electron microscopy disclosed interruptions of the bile canalicular membrane, consistent with this disease. There was also a remarkable increase of microfilamentous structures in the pericanalicular ectoplasm and in the hepatocytic cytoplasm. These findings suggest that the cause of cholestasis is a disturbance in bile acid secretion, entailing a hypertrophy of pericanalicular microfilaments, which are thought to play a role in the final step of biliary secretion.

2090 JAUNDICE AND BRIDGING CENTRILOBULAR NECROSIS OF LIVER IN CIRCULATORY FAILURE. (Eng.) Buhac, I.; Agrawal, A. B.; Park, S. K.; Lomotan, A.; Lowen, B.; Balint, J. A. (Veterans Admin. Hosp., Albany, NY). *N.Y. State J. Med.* 76 (5):678-682; 1976.

The incidence of centrilobular liver necrosis, and its clinical relevance, were studied in postmortem material from 2,264 autopsies (1966-1972) and from a further 4,227 autopsies (1952-1965). In the group of 2,264, centrilobular liver necrosis was found in 15.5% of the cases. Extensive centrilobular necrosis with bridging by necrotic tissue between the adjacent lobules was seen in 3.7% of these cases, and in 0.6% of the cases, bridging centrilobular necrosis was associated with evident jaundice. In the additional 4,227 autopsied patients, jaundice and centrilobular necrosis were found in 0.8% of the cases. Thus, among 6,491 autopsies, bridging centrilobular necrosis was identified as the cause of clinical hyperbilirubinemia (3-28.5 mg/100 ml in 48 cases, or 0.7%). Congestive heart failure secondary to arteriosclerotic heart disease was the most common cause of centrilobular necrosis associated with jaundice. Differentiation of the centrilobular necrosis of the liver associated with jaundice from other types of hepatogenous jaundice is very difficult, and the only way to obtain a secure diagnosis seems to be by liver biopsy.

2091 FAMILIAL OCCURRENCE OF GIANT CELL HEPATITIS IN INFANCY. (Eng.) Sandor, T.; Surinya, M.; Monus, Z. (Univ. Medicine, Pf. 401, 6701 Szeged, Hungary). *Acta Hepatogastroenterol. (Stuttg.)* 23(2):101-104; 1976.

The case of an infant girl with giant cell hepatitis (GCH) is presented. The child's brother died from primary hepatic cancer complicating giant cell hepatitis. The patient protracted neonatal jaundice, which recurred at age 3 months, and abnormal liver function tests. Histologic examination revealed the lobular structure of the liver to be broken down, extensive giant cell transformation, and connective tissue septa extending irregularly from portal tracts into surrounding parenchyma. One year later, the typical giant cells were no longer found, and a morphologically pronounced cholestasis was demonstrated. At surgery for cholelithiasis, definite histologic evidence of cirrhosis with cholestasis was found. The child died at the age of 3.5 yr in a hepatic coma. Although there is no clinical or histological difference between familial and sporadic GCH, it is suggested that the familial form has a poorer prognosis and that the disease is more malignant and has a more rapid course for the first-born child.

2092 SPONTANEOUS HEPATIC ARTERY THROMBOSIS WITH INFARCTION OF THE LIVER. (Eng.) O'Connor, P. J.; Buhac, I.; Balint, J. A. (Albany Medical Coll., Albany, NY 12208). *Gastroenterology* 70(4): 599-601; 1976.

Extensive infarction of the liver, initially thought to be halothane hepatitis, is described in an 80-yr-old man. The patient described severe right upper quadrant abdominal pain and abnormal liver function tests after leg amputation, under halothane anesthesia. Diagnosis was accomplished by percutaneous needle biopsy of the liver, which demonstrated a large area of vascular necrosis. Despite the ischemic injury, the liver function improved while the patient was adequately oxygenated and maintained in fluid and electrolyte balance. The patient died 9 days after surgery, from an acute myocardial infarction. Autopsy showed thrombosis of the celiac trunk with extension into the splenic, common hepatic, and right and left hepatic arteries. Approximately 50% of the hepatic parenchyma was replaced by infarcted tissue. It is suggested that the liver infarction was caused by the patient's inability to maintain an adequate oxygen content of portal venous blood, at the time of thrombosis of the hepatic artery, due to underlying heart disease and obstructive pulmonary disease.

2093 LIVER DYSFUNCTION AND POLYMYALGIA RHEUMATICA. A CASE REPORT. (Eng.) Kosolcharoen, P.; Magnin, G. E. (Univ. Wisconsin Medical Sch., Madison, WI 54449). *J. Rheumatol.* 3(1):50-53; 1976.

The case of a 65-yr-old woman with the polymyalgia rheumatica syndrome and liver dysfunction is described. The patient presented with muscle pain and weakness. Biopsy disclosed several small capillaries that were heavily infiltrated by mononucleated cells and muscle fibers that showed centralization, increase in sarcolemal nuclei, and lipid vacuolization. Liver biopsy demonstrated granuloma formation and massive infiltration of the portal spaces with lymphocytes; in addition, there was a significantly elevated alkaline phosphatase. The patient improved within 3 days of commencing treatment with prednisone (20 mg/day). This case supports the concept that liver dysfunction can occur in polymyalgia rheumatica without underlying secondary illness.

2094 THE VISIBLY FATTY LIVER. (Eng.) Griscom, N. T.; Capitanio, M. A.; Wagoner, M. L.; Culham, G.; Morris, L. (Harvard Medical Sch., Boston, MA). *Radiology* 117(2):385-389; 1975.

Four cases of fatty infiltration of the liver, identified roentgenographically, are reported in children ranging in age from 2 to 19 months. In each case, the first sign was radiolucency of the liver. Cystic fibrosis was diagnosed in one case. Radiological recognition of fatty infiltration has only occurred in young children, thus far.

2095 PELIOSIS HEPATIS. (Eng.) Pliskin, M. (General Hosp. Monroe County, East Stroudsburg, PA). *Radiology* 114(1):29-30; 1975.

The case of a 27-yr-old woman with peliosis hepatis is presented. The late arterial phase of a superior mesenteric injection for arteriography showed multiple small accumulations of contrast material, which became more prominent in the parenchymal and venous phases. Histologically, the condition is characterized by multiple blood-filled cystic spaces that may be lined by endothelium. Although the clinical manifestations of peliosis hepatis are nonspecific, the angiographic findings were prominent and distinctive in the present case. The author concludes that the angiographic appearance of multiple, small diffuse hemangiomas together with the absence of tumor vessels, vascular displacement or encasement, and venous occlusion should distinquish peliosis hepatis from neoplasms.

2096 METABOLIC MECHANISMS IN REYE SYNDROME. END OF A MYSTERY? (Eng.) Thaler, M. M. (Dept. Pediatrics, Univ. California, San Francisco, CA 94116). *Am. J. Dis. Child.* 130(3):241-246; 1976.

Research concerning the Reye syndrome is reviewed. Clinical observations suggest that: the evolution of this syndrome appears to be a function of injury sustained during the earliest phase of the disease, and the severity of the main illness reflects the extent of the initial insult; ammonia may be responsible for the early neurotoxic effects that determine the eventual outcome; and visceral damage, as distinct from selective metabolic deficiency, may develop concurrently with the central nervous system lesion or thereafter, and may also be due to the effects of ammonia. Examination of the enzymes involved in the conversion of ammonia to urea in liver biopsy specimens of patients with the Reye syndrome suggests that a majority of patients may suffer from an inherited or induced defect in ammonia metabolism located in the mitochondria. It is suggested that the postulated deficiencies in the urea cycle may be overcome with oral administration of ornithine, or of its precursor, arginine. In addition, citrulline may enhance removal of ammonia by an alternate pathway.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

2122 SIGNIFICANCE OF HYPERBILIRUBINEMIA IN ACUTE CHOLECYSTITIS. (Eng.) Dumont, A. E. (New York Univ. Sch. Medicine, New York, NY). *Surg. Gynecol. Obstet.* 142(6):855-857; 1976.

The incidence and significance of hyperbilirubinemia were examined in 110 patients who had symptoms of acute cholecystitis and underwent laparotomy. Thirty-two patients had abnormally elevated serum bilirubin levels on admission. Surgical or roentgenographic examination of the common duct, or both, in 19 of these patients disclosed stones in 13. Serum levels of bilirubin averaged 6.1 mg% in those with stones and 2.7 mg% in the others. In the remaining 13 patients, the common duct was not examined, but elevated bilirubin levels, averaging 2.6 mg%, quickly returned to normal values. Hyperbilirubinemia significantly increases the likelihood of finding common duct stones in patients with acute cholecystitis, although it also occurs frequently in patients with acute cholecystitis without common duct stones. The latter situation may depend on an alteration in the normal impermeability of epithelium of the gallbladder to conjugated bilirubin.

2123 EFFECT OF DIETARY COMPOSITION ON THE UNCONJUGATED HYPERBILIRUBINAEMIA OF GILBERT'S SYNDROME. (Eng.) Gollan, J. L.; Bateman, C.; Billing, B. H. (Royal Free Hosp., Pond St., Hampstead, London NW3 2QG, England). *Gut* 17(5):335-340; 1976.

The influence of dietary composition on the unconjugated hyperbilirubinemia of Gilbert's syndrome was studied in 29 patients. After a period on a normal diet (10 MJ), an i.v. infusion of 40% glucose (8.4 MJ) together with a 1.6 MJ p.o. diet for 2 days resulted in an increment in plasma bilirubin concentration of 127 ± 18% above the basal level. Both the administration of i.v. Intralipid (20%) and the return to a normal diet caused a prompt reversal of this glucose effect. An increment of 135 ± 10% in plasma bilirubin concentration was obtained when a standard "fasting" diet (1.6 MJ) was given for 2 days. When the lipid content of this fasting diet was increased from 33% to 85%, the rise in plasma bilirubin was only 49 ± 19%. A 10 MJ p.o. diet for 3 days, which contained most of its energy content as carbohydrate and only 0.6% as lipid, produced a 76 ± 12% increase in plasma bilirubin concentration. When the lipid content of the diet was increased to 9% of the energy intake, no significant change from the basal level was observed. These findings support the hypothesis that the hyperbilirubinemia associated with both carbohydrate feeding and fasting is attributable, at least in part, to lipid withdrawal. Although a restricted dietary intake or the parenteral administration of lipid-free solutions has a marked effect on the hyperbilirubinemia of patients with Gilbert's syndrome, normal daily variation in dietary composition is unlikely to cause a significant change. The influence of different feeding regimes on neonatal hyperbilirubinemia requires investigation.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

2129 EPIDEMIOLOGICAL STUDIES OF PVC MANUFACTURERS AND FABRICATORS, AND PRIMARY ANGIOSARCOMA OF THE LIVER. (Eng.) Baxter, P. J. (Baynards House, 1 Chepstow Place, London W2 4TF, England). *Proc. R. Soc. Med.* 69(4):297-299; 1976.

A prospective study of polyvinyl chloride (PVC) manufacturers, a prospective study of PVC fabricators, and a retrospective study of primary angiosarcoma of the liver, to determine any relation between the risk of occupational exposure to vinyl chloride and the development of primary liver angiosarcoma are described. Prospective mortality and cancer registration studies to test hypotheses concerning the carcinogenicity of vinyl chloride in other sites, such as the lung and brain, are also discussed. In the absence of a satisfactory objective test for use in morbidity surveys, mortality data should enable the assessment of more serious complications of periportal fibrosis due to vinyl chloride.

2130 MEDICAL SURVEILLANCE OF VINYL CHLORIDE WORKERS. (Eng.) Duck, B. W. (BP Res. Center, Sunbury on Thames, TW16 7LN, U.K.). *Proc. R. Soc. Med.* 69(4):307-309; 1976.

A clinical survey was undertaken in 1,357 vinyl chloride (VC) workers and 429 workers without VC exposure from six polymerization plants, following reported cases of angiosarcoma of the liver among workers exposed to VC. The initial examination comprised medical history, physical examination, biochemical tests (SGOT, SGPT, GGTP, alkaline phosphatase, and bilirubin), platelet count, and urinalysis. Initial liver function test abnormalities were found in 12.5% of the VC workers and in 16.5% of the controls. Repeat tests on VC workers with abnormal findings revealed persistent abnormalities in about one-third of these individuals (56 men). Thus far no obvious liver disease due to vinyl chloride exposure was identified, but the procedure enabled individuals with persistent liver dysfunction to be detected and removed from VC exposure. It is recommended that to be effective, liver function tests should: yield positive findings at an early stage of disease; produce few false positive and negative results; be able to differentiate between pathological conditions due to VC and to other causes, such as alcohol.

2131 EPIDEMIOLOGICAL STUDIES OF VINYL CHLORIDE HEALTH EFFECTS IN THE UNITED STATES. (Eng.) Falk, H.; Waxweiler, R. J. (Dept. Health, Education, Welfare, Atlanta, GA 30333). *Proc. R. Soc. Med.* 69(4):303-306; 1976.

Three epidemiological studies of the effects of vinyl chloride (VC) in the United States are reviewed. Age and sex differences in hepatic angiosarcoma were consistent with the hypothesis that occupational exposure is a more significant cause of hepatic angiosarcoma than of non-angio hepatic sarcoma. A cross-sectional medical screening examination of 130 workers at a polyvinyl chloride (PVC) polymerization plant showed no significant differences between the workers and controls in any of six liver function tests (SGOT, bilirubin, alkaline phosphatase, LDH, GGTP, and ornithine carbamyl transferase). In a cohort mortality study at four PVC polymerization plants, 12 cases of lung cancer were discovered. However, lung cancer did ot correlate as highly with VC exposure as did epatic angiosarcoma. It is suggested that some dditional chemical exposure at these plants may be orking together with VC, or separately, to produce his effect.

2132 JAUNDICE DUE TO CARBIMAZOLE. (Eng.) Lunzer, M.; Huang, S. N.; Ginsburg, J.; hmed, M.; Sherlock, S. (1120 HSW, Univ. California, an Francisco, CA 94143). *Gut* 16(11):913-917; 1975.

he case report of a 63-yr-old woman who developed aundice due to carbimazole is presented. On three ccasions, the patient, who had hyperthyroidism, eveloped a reaction that included fever, pruritus, alaise, and, on one occasion, jaundice 1-17 days after taking carbimazole (5 mg tds). Challenge with carbimazole (2 x 5 mg) was followed within 12 hr y abdominal pain, pruritus, and increased serum transaminase levels. Light microscopy of a percutaneous liver biopsy showed increase of portal zone cellularity over the control. Electron microscopy revealed fine structural changes compatible with drug-related liver injury; the liver cells showed a marked degree of proliferation of smooth endoplasmic reticulum, segmental fusiform dilatation of the cisternae of the granular endoplasmic reticulum, numerous small autophagic vacuoles, and "blistering" of the mitochondrial membranes. It is concluded that jaundice is an extremely rare complication of carbimazole therapy.

2133 DANTROLENE HEPATITIS. (Eng.) Schneider, R.; Mitchell, D. (St. Thomas Hosp., 4220 Harding Rd., Nashville, TN 37202). *JAMA* 235(15): 1590-1591; 1976.

The case of a 38-yr-old woman who developed hepatitis following treatment with dantrolene sodium for multiple sclerosis is presented. The patient had received dantrolene for 4 months, at a maximum dose of 400 mg/day. During treatment, she felt weak with mild malaise. She developed severe jaundice, and her total serum bilirubin level reached 32.8 mg/100 ml, 16 days after the treatment was discontinued. Menghini suction liver biopsy revealed swelling, vacuolation, and ballooning of pericentral hepatocytes, and many binucleate forms were observed. The patient was believed to have a cholestatic hepatitis secondary to dantrolene therapy. Serum bilirubin returned to normal after over 3 months. It is recommended that this drug be used with caution in people with liver disease, and that liver function be monitored in all patients who receive dantrolene.

2134 POSSIBLE HEPATOTOXICITY OF DOXIDAN. (Eng.) Tolman, K. G.; Hammar, S.; Sannella, J. J. (Univ. Utah Coll. Medicine, 50 North Medical Drive, Salt Lake City, UT 84132). *Ann. Intern. Med.* 84(3): 290-292; 1976.

The case of a 24-yr-old woman who developed leukopenia and liver disease while taking Doxidan (a laxative containing 1,8-hydroxyanthraquinone and dioctyl calcium sulfosuccinate) is reported. The patient took the drug for 1 yr prior to presentation with anorexia, vomiting, headaches, and a syncopal episode; she had increased the dose from one capsule/day to four capsules/day, 3 weeks before hospitalization. Alkaline phosphatase was 339 IU. A liver biopsy revealed chronic inflammatory cell infiltrate invading adjacent hepatic parenchyma. The infiltrate was associated with focal hepatocellular necrosis, creating a histologic pattern of chronic aggressive hepatitis. There was a granular deposit of IgE that was heaviest within the Kupffer cells. Liver function returned to normal when the drug was discontinued. When the patient was experimentally rechallenged with Doxidan (50 mg 1,8-hydroxyanthraquinone plus 60 mg dioctyl calcium sulfosuccinate, one capsule/day), alkaline phosphatase again increased. Heat fractionation showed that the alkaline phosphatase was 85% hepatobiliary. It is suggested that dioctyl calcium sulfosuccinate may have potentiated the toxicity. The finding of IgE deposition may suggest a causal relation between IgE and the hepatocellular necrosis. The mechanism of toxicity remains unclear.

2135 A NITROFURANTOIN-INDUCED DISORDER STIMULATING CHRONIC ACTIVE HEPATITIS: A CASE REPORT. (Eng.) Fagrell, B.; Strandberg, I.; Wengle, B. (Karolinska Institutet at Serafimerlasarettet, Stockholm, Sweden). *Acta Med. Scand.* 199(3): 237-239; 1976.

A 78-yr-old woman with liver damage resembling chronic active hepatitis occurring during long-term (4 yr) nitrofurantoin treatment (50 mg, 1-3 times/day) is described. On admission to the hospital she displayed jaundice, ascites, and high serum levels of SGOT, SGPT, bilirubin, and γ-globulin as well as high titers of antinuclear factor, and antibodies against smooth muscle cells. After withdrawal of nitrofurantoin, the clinical and laboratory picture normalized without corticosteroid treatment, suggesting that the liver reaction was drug-induced. It is concluded that drug reactions should be considered among the etiological factors of chronic active hepatitis and that nitrofurantoin administration should be avoided in such cases.

2136 LIVER DAMAGE IN SCARLET FEVER: DESCRIPTIONS OF TWO AFFECTED CHILDREN. (Eng.) Kocak, N.; Ozsoylu, S.; Ertugrul, M.; Ozdol, G. (Hacettepe Univ., Faculty Medicine, Ankara, Turkey). *Clin. Pediatr. (Phila.)* 15(5):462-464; 1976.

Two cases of scarlet fever, in which hepatitis became apparent during the acute phase, are described. Two girls aged 9 and 12 yr had palpable livers, jaundice, bilirubinuria, and abnormal liver function tests. A needle biopsy of the liver in the second patient showed polymorphonuclear leukocyte infiltration in the portal area, with degenerative changes in the hepatocytes. Most symptoms disappeared by the 11th or 12th day in both patients. Since the cases of hepatitis occurred during the early phase of scarlet fever without associated conditions, it is suggested that it was a rare complication of liver toxicity.

2137 GRANULOMATOUS HEPATITIS CAUSED BY B.C.G. DURING IMMUNOTHERAPY FOR A MALIGNANT MELANOMA. (Fre.) Serrou, B.; Michel, H.; Dubois, J.-B.; Serre, A. (No affiliation given). *Arch. Fr. Mal. App. Dig.* 64(3):287-288; 1975.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

2140 MORPHOLOGY OF THE GB HEPATITIS AGENT. (Eng.) Almeida, J. D.; Deinhardt, F.; Holmes, A. W.; Peterson, D. A.; Wolfe, L.; Zuckerman, A. J. (Wellcome Res. Lab., Langley Park, Beckenham, Kent BR3 3BS, England). *Nature* 261(5561): 608-609; 1976.

The sera of marmosets were inoculated with serum from a patient who developed mild acute hepatitis, and the GB hepatitis agent was isolated and examined electron microscopically. The GB isolate had a peak size distribution between 20-22 nm; this agent was smaller than another hepatitis isolate, MS-1 (hepatitis A). GB was also more fragile, as crescent-shaped forms were a recurrent feature, whereas these forms were not seen in the MS-1 agent. The infectious GB serum also reacted with convalescent serum, revealing a few relatively small aggregates (immune complexes) of particles. It is concluded that the GB agent does not belong morphologically to either hepatitis A or B, and it may well be a third agent causing viral hepatitis in man.

2141 DETECTION OF VIRAL HEPATITIS TYPE A. (Eng.) Hollinger, F. B.; Bradley, D. W.; Dreesman, G. R.; Melnick, J. L. (Baylor Coll. Medicine, Houston, TX 77030). *Am. J. Clin. Pathol.* 65(5):854-865; 1976.

A microtiter solid phase immunoradiometric assay (micro-SPIRA) developed for detecting hepatitis A (HAAg) and anti-HA was evaluated in acute phase human stool specimens or marmoset liver homogenates containing hepatitis A virus particles. The method involved the coupling of unlabeled immunoglobulin containing anti-HA to the insoluble polyvinyl matrix of a microtiter well, enabling extraction of the immunologically reactive HA antigen from the unknown sample. bound antigen was measured, following interaction wit radiolabeled ^{125}I-immunoglobulin G preparation containing anti-HA. Coincident peaks of radioactivity and hepatitis A virus (HAV) particle counts were obtained by micro-SPIRA and immunoelectronmicroscopy, with the major proportion of the antigenic activity o curring at bouyant densities between 1.31-1.35 g/cm^3 in human stools and 1.27 g/cm^3 in liver preparations. Specificity for HAV antigen was confirmed by a blocking test in which the HA antigenic reaction was inhibited by convalescent sera, but not by pre-immune sera obtained from four volunteers who were experimentally infected with HAV. It is concluded that the application of the micro-SPIRA technique to the detection of HAV antigen and its antibody provides a means for diagnosing viral hepatitis type A and for studying the pathogenesis of this disease.

2142 MUSSEL-ASSOCIATED VIRAL HEPATITIS, TYPE A: SEROLOGICAL CONFIRMATION. (Eng.) Dienstag, J. L.; Lucas, C. R.; Gust, I. D.; Wong, D. C.; Purcell, R. H. (Natl. Insts. Health, Building 7, Room 301, Bethesda, MD 20014). *Lancet* 1 (7959):561-563; 1976.

Seven members of a family of 14 developed acute viral hepatitis approximately 1 month after 10 members ate incompletely cooked mussels. There was a statistically significant difference in attack rates between mussel-ingesters (70%) and noningesters (0%, $p=0.035$). The etiological role of hepatitis-A virus, suspected on epidemiological grounds, was serologically confirmed by the demonstration of rises in titers of serum-antibody to hepatitis-A antigen (serologically related to the MS-1 strain of hepatitis-A virus), determined by immune adherence hemagglutination.

2143 HBc AND HBs ANTIGEN IN HEPATOCYTES.

(Eng.) Shikata, T.; Yoshizaki, C.; Okazaki, K.; Uzawa, T.; Matsushita, H.; Toyokawa, S.; Takahashi, T.; Gotoh, A. (Faculty Medicine, Univ. Tokyo, Hongo, Bunkyo-ku, Tokyo 113, Japan). *Gastroenterol. Jpn.* 10(3):199-207; 1975.

The relation between the electron microscopic structures and the immunofluorescent appearance of hepatitis B (HB) antigen found in the hepatocytes of patients with HB antigenemia was studied. The hepatocyte nuclei, containing numerous virus-like particles, showed positive immunofluorescence by antiserum against the core of Dane particles. The areas in which filamentous structures were observed in the cisternae of endoplasmic reticulum and hyaloplasma corresponded to orecein- or aldehyde-fuchsin-positive substances in the light microscope. However, a direct relation between filamentous structures and HB surface antigen is still obscure. It is concluded that virus-like particles in the nucleus correspond to core and filamentous structures in the cytoplasma correlate with coat protein of hepatitis B virus.

2144 THE LOCALISATION OF HEPATITIS B ANTIGEN AND IMMUNOGLOBULIN G IN LIVER TISSUE: AN IMMUNOFLUORESCENCE, LIGHT AND ELECTRON MICROSCOPIC STUDY.

(Eng.) Roos, C. M.; Feltkamp-Vroom, T. M.; Helder, A. W. (Central Lab. Netherlands Red Cross Blood Transfusion Service, P.O.B. 9190, Amsterdam, the Netherlands). *J. Pathol.* 118(1):1-8; 1976.

Liver tissue specimens from 43 hepatitis B antigen (HBAg) seropositive patients and 22 HBAg seronegative individuals were investigated for the presence of HBAg, using the immunofluorescence technique. Histological diagnoses were established with light microscopy on routinely stained frozen liver sections. The liver specimens of 42 of the 43 HBAg-positive patients showed positive fluorescence. Three distinct fluorescence patterns were observed: diffuse, focal, and solitary. The diffuse pattern appeared to occur particularly in chronic aggressive or persistent hepatitis. The focal pattern was seen only in the group of patients without obvious alterations, and the solitary pattern was seen especially in acute hepatic necrosis. Fifteen out of the 42 HBAg-positive liver specimens were investigated with the electron microscope. Eight of 15 HBAg-positive liver specimens had approximately 23 nm nuclear particles. In these eight cases, nuclear IgG was observed with the immunofluorescence technique. It was also observed in 14 other specimens, which were studied with the electron microscope. It is suggested that immune complexes consisting of virus-core antigen and IgG are present in the nuclei of hepatocytes.

2145 HEPATITIS B SURFACE ANTIGEN AND ANTIBODY IN ASYMPTOMATIC BLOOD DONORS.

(Eng.) Sinclair, J. C.; Feinman, S. V.; Wrobel, D. M.; Berris, B. (Dept. Medicine, Univ. Toronto, Suite 427, 600 Univ. Ave., Toronto, M5G 1X5, Ontario, Canada). *JAMA* 235(10):1014-1017; 1976.

Seventy-two volunteer blood donors who had hepatitis B surface antibody (anti-HBs) were studied and compared with 115 carriers of hepatitis B surface antigen (HBsAg). Anti-HBs-positive donors gave a history of greater possible exposure to hepatitis B virus (32 of 72 in comparison with 17 of 115, $p<0.01$). There was a lower male-female ratio in the anti-HBs-positive donors (1.7:1 compared to 3.6:1), and they had a much lower frequency of abnormal hepatic function test results; 46% of carriers had abnormal results, while only 18% of the antibody-positive group had minimal abnormalities. Those who were positive by counterimmunoelectrophoresis (CIEP), which indicated a high titer of antibody (>1:2,000, as measured by passive hemagglutination assay), also had an ethnic origin similar to that of the donor panel, i.e., predominantly Canadian and northern European. A majority of the HBsAg carriers, on the other hand, had origins in the Mediterranean and Far Eastern countries. Low antibody-titer (positive passive hemagglutination assay but negative CIEP) donors had ethnic origins that more closely approximated those of HBsAg carriers. These ethnic differences may be due to genetic factors, to a difference in degree of antigen-antibody complexing, or to exposure to hepatitis B in the low titer group during the early years of life.

2146 LACK OF AN AUTOSOMAL RECESSIVE GENETIC INFLUENCE IN VERTICAL TRANSMISSION OF HEPATITIS B ANTIGEN.

(Eng.) Stevens, C. E.; Beasley, R. P. (New York Blood Center, 310 East 67th St., New York, NY 10021). *Nature* 260(5553):715-716; 1976.

The rates of hepatitis B antigenemia among children in two groups of families--those in which both parents were hepatitis B antigen (HBsAg) carriers and those in which the mother was a carrier, but the father's serum was antibody (anti-HBs)-positive--were compared to determine whether the predisposition to the HBsAg carrier state is inherited as an autosomal recessive gene. HBsAg was detected by radioimmunoassay, and anti-HBs was detected by passive hemagglutination. Babies in both groups were followed from birth for the same period of time (mean, 12 months), and none of the babies or their siblings had clinical hepatitis. Twenty-two out of 27 babies retested after the first positive specimens (8 of 9 with an antigen-carrier father and 14 out of 18 with an antibody-positive father) remained HBsAg carriers. An additional baby in each group

LIBRARY U. OF I.

developed anti-HBs (neither had had previously detected antigenemia). Thus, the frequency of antigenemia among the offspring was unrelated to whether the father's serum was antigen or antibody positive. The data seem to be incompatible with an autosomal recessive mode of inheritance for HBsAg carrier predisposition, as all offspring of families in which both parents were antigen carriers would have had to be homozygous for carrier predisposition. It is suggested that the infectious dose and the age when infection occurs are more important determinants of the carrier state.

2147 CHRONIC CARRIERS OF HEPATITIS B ANTIGEN (HBsAg): HISTOLOGICAL, BIOCHEMICAL, AND IMMUNOLOGICAL FINDINGS IN 31 VOLUNTARY BLOOD DONORS.

(Eng.) Villeneuve, J. P.; Richer, G.; Cote, J.; Guevin, R.; Marleau, D.; Joly, J. G.; Viallet, A. (Hopital Saint-Luc, 1058, St-Denis St., Montreal, P. Quebec, Canada). *Am. J. Dig. Dis.* 21(1):18-25; 1976.

Thirty-one hepatitis B surface antigen (HBsAg) carriers submitted to liver biopsy. They were followed for a period of 10-33 months, and all remained positive for HBsAg. Fifteen of these 31 subjects had lived in institutions during infancy or childhood, and none were drug users. Histological examinations revealed 24 cases of chronic persistent hepatitis (CPH), 2 cases of chronic aggressive hepatitis, 2 patients with steatosis, and 3 patients with normal liver. On repeated determination, 16 of the 31 subjects had at least 1 elevated transaminase level. Transaminase levels were not correlated with the histological diagnosis. Four cases had positive antinuclear antibodies, all in the CPH group, a finding that was not correlated with any clinical, biological, or histological findings. The search for other auto-antibodies and the immunoglobulin determinations were inconclusive. It appears that chronic HBsAg carriers often have chronic hepatitis, usually persistent, occasionally aggressive; liver biopsy still remains the most useful approach in the evaluation of these HBsAg carriers.

2148 HEPATITIS B IMMUNE GLOBULIN AS A PROPHYLACTIC MEASURE FOR SPOUSES EXPOSED TO ACUTE TYPE B HEPATITIS.

(Eng.) Redeker, A. G.; Mosley, J. W.; Gocke, D. J.; McKee, A. P.; Pollack, W. (John Wesley County Hosp., 2826 South Hope St., Los Angeles, CA 90007). *N. Engl. J. Med.* 293(21): 1055-1059; 1975.

A control human immune globulin preparation and one identified as HBIG (with a high concentration, 442 μg/ml, of antibodies to surface components of hepatitis B virus) were assessed in a double-blind experiment. Effectiveness was tested in 100 sexual partners of 96 patients with acute type B hepatitis. Within 150 days after injection, 9 of 33 sexual partners in the control group had symptomatic type B hepatitis, compared with 1 of 25 persons receiving HBIG. One non-B case also occurred in the HBIG group. Five control globulin recipients had evidence of subclinical hepatitis B infection, compared with one HBIG recipient. Thus, HBIG appears effective in suppressing not only disease, but also infection itself.

2149 DETECTION OF SURFACE AND CORE ANTIGENS OF HEPATITIS B VIRUS IN THE LIVER OF 164 HUMAN SUBJECTS. A STUDY BY IMMUNOPEROXIDASE AND ORCEIN STAINING.

(Eng.) Lamothe, F.; Laurencin-Piche, J.; Cote, J.; Guevin, R.; Viallet, A.; Richer, G. (Hopital Saint-Luc, 1058 St. Denis St., Montreal, Quebec, H2X 3J4, Canada). *Gastroenterology* 71(1):102-108; 1976.

Liver specimens from 126 patients hospitalized for various conditions and from 38 hepatitis B surface antigen (HBsAg) chronic carriers were investigated for the presence of HBsAg and hepatitis B core antigens (HBcAg). Orcein staining was used on fixed and frozen material and direct immunoperoxidase was used on frozen material, with antisera specific for surface (anti-HBs) and core (anti-HBc) antigens of HBV. No liver staining was found in the 98 HBsAg-seronegative patients. Among the 28 HBsAg seropositive patients, only 3 showed positive staining: 1 patient with acute viral hepatitis showed nuclear staining with anti-HBc, 2 patients with postnecrotic cirrhosis showed cytoplasmic staining with anti-HBs and/or orcein, and 1 of them also showed nuclear staining with anti-HBc. Among the 38 chronic carriers, 25 showed positive cytoplasmic staining with anti-HBs and/or orcein, while 1 patient (with chronic aggressive hepatitis) also showed nuclear staining with anti-HBc. Anti-HBs and orcein staining are equally sensitive and specific for the detection of HBsAg in hepatocytes; the authors attribute conflicting results to sampling error of distribution of HBsAg in small liver fragments.

2150 CAN GASTROINTESTINAL ENDOSCOPY TRANSMIT HEPATITIS B TO PATIENTS?

(Eng.) McDonald, G. B.; Silverstein, F. E. (Veterans Admin. Hosp., 4435 Beacon Ave. South, Seattle, WA 98108). *Gastrointest. Endosc.* 22(3):168-170; 1976.

Peroral endoscopy was performed on a jaundiced patient who was later found to have type B hepatitis. Before this diagnosis was made, four patients had been endoscoped with the same instrument. The endoscope had been cleansed with soapy water (0.25% hexachlorophene) and 70% isopropyl alcohol between examinations. None of the four patients developed laboratory or clinical signs of hepatitis B infection during 6 months of observation, suggesting that routine cleansing procedures may prevent passage of hepatitis virus. It is concluded that there is no practical method for sterilizing fiberoptic instruments to kill the hepatitis B virus. It is suggested that the sera of all jaundiced patients be tested for hepatitis B antigen, prior to endoscopy. If a patient is found to be positive, endoscopy should not be performed.

2151 HBsAg-NEGATIVE HEPATITIS IN A HEMODIALYSIS UNIT: RELATION TO EPSTEIN-BARR VIRUS.

(Eng.) Corey, L.; Stamm, W. E.; Feorino, P. M.; Bryan, J. A.; Weseley, S.; Gregg, M. B.; Solangi, K. (Center Disease Control, Atlanta, GA 30333). *N. Engl. J. Med.* 293(25):1273-1278; 1975.

An epidemiologic investigation was undertaken when 11 of 40 patients in a hemodialysis unit developed clinical or biochemical evidence of hepatitis during a 5-week period. The clinical disease was mild, being limited solely to dialysis patients. The incubation period was between 17-35 days, and 10 of 11 patients had been exposed to a single venous-pressure monitor before onset. Dried blood and evidence of blood reflux to the venous-pressure gauge suggested that cross-contamination of the blood of successive patients probably resulted in disease transmission. No association with the hepatitis B surface antigen or anti-hepatitis B antibody was domonstrated, but 10 of the 11 patients with elevated transaminase levels had evidence of recent exposure to Epstein-Barr virus as manifested either by Ox-cell hemolysin titers or rises in titers to viral capsid antigen. The study demonstrates a relation between clinical hepatitis, elevated transaminase levels, and serologic evidence of recent infection with Epstein-Barr virus in patients on chronic hemodialysis.

2152 SYNTHESIS RATES OF ALBUMIN AND FIBRINOGEN DURING AND AFTER ACUTE HEPATITIS. (Eng.)

Mayer, G.; Schomerus, H. (Dept. Internal Medicine, Univ. Marburg, Marburg a.d. Lahn, W. Germany). *Digestion* 13(5):261-271; 1975.

Synthesis rates of albumin and fibrinogen were determined in six patients with acute viral hepatitis and in nine control patients using a ^{14}C carbonate method that was based on the hepatic-urea cycle. Five patients were restudied several weeks after complete recovery. The mean albumin and fibrinogen synthesis rates in the control group were 238.8 and 23.5 mg/kg/day, resp. In two patients with mild courses of hepatitis and in one patient studied during the early phase of a rapid and fatal course, the albumin synthesis rate during the acute disease did not differ from controls, whereas the fibrinogen synthesis rate was slightly increased. Three patients with severe hepatitis showed a definite decrease in albumin and fibrinogen synthesis rates, the lowest value being 76 mg/kg/day for albumin and 6.3 mg/kg/day for fibrinogen. The decrease in plasma protein synthesis correlated neither with serum transaminase or bilirubin levels nor with plasma albumin or fibrinogen concentrations during the acute phase. The two patients with the lowest albumin and fibrinogen synthesis rates also showed a definite decrease of the prothrombin index during the acute phase. Both patients presented very prolonged courses of the disease. In all patients studied twice, plasma protein synthesis rates were normal after recovery. These results suggest that the synthesis of secretory proteins is decreased in severe acute hepatitis.

2153 HEPATITIS B IMMUNE GLOBULIN--PREVENTION OF HEPATITIS FROM ACCIDENTAL EXPOSURE AMONG MEDICAL PERSONNEL.

(Eng.) Grady, G. F.; Lee, V. A. (Natl. Heart and Lung Inst., Bethesda, MD 20014). *N. Engl. J. Med.* 293(21):1067-1070; 1975.

The role of antibody against hepatitis B surface antigen (HB$_s$Ag) in reducing the probability of hepatitis after accidental exposure to serum from patients with hepatitis or carriers of HB$_s$Ag was studied prospectively among 712 medical workers. One-fourth of the workers were anti-HB$_s$-positive, and less than 1% of them developed hepatitis, in contrast to 11% of those who were anti-HB$_s$-negative. Three coded immune-serum globulin preparations of varying anti-HB$_s$ titer were randomly assigned. Among 251 persons passively immunized with globulin having a conventionally low anti-HB$_s$ titer, hepatitis developed in 7% within 6 months. Comparative rates among those receiving intermediately high titer and high titer globulin, resp., were 5% and 2%. The significantly lower incidence among the latter ($p<0.05$) was offset by six additional cases, all in recipients of high titer globulin, detected when follow-up was extended to 9 months. Thus, a randomized controlled trial demonstrated a significantly lower incidence of hepatitis after accidental inoculations of high anti-HB$_s$ titer globulin than normal globulin.

2154 ALTERED ELIMINATION OF ANTIPYRINE IN PATIENTS WITH ACUTE VIRAL HEPATITIS.

(Eng.) Burnett, D. A.; Barak, A. J.; Tuma, D. J.; Sorrell, M. F. (San Francisco Sch. Medicine, San Francisco, CA 94143). *Gut* 17(5):341-344; 1976.

The plasma half-life and clearance of antipyrine was investigated in six patients during the acute phase and again during the recovery phase of viral hepatitis. Each patient served as his own control, thereby eliminating genetic factors and minimizing environmental factors that cause large interindividual variations in antipyrine elimination rates. Liver function tests, antipyrine, half-life, plasma clearance, and the apparent volume of distribution were determined in the acute and recovery period. The apparent volume of distribution of antipyrine did not change in five of the six patients as they recovered. Five of the six patients showed prolonged plasma half-lives and decreased plasma clearance of the drug at the time of acute illness, and these parameters reached normal values during recovery. The plasma half-life and clearance of the drug did not correlate with biochemical indices of liver function in the acute or recovery phase. This supports the concept that drug metabolism is frequently impaired in liver disease.

2155 5'-NUCLEOTIDE PHOSPHODIESTERASE ISOENZYME IN PATIENTS WITH HEPATITIS B INFECTION.

(Eng.) Tsou, K. C.; McCoy, M. G.; Lo, K. W.; London, W. T. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Cancer Res.* 35(9):2361-2364; 1975.

LIBRARY U. S.

The etiologic relation of hepatitis B infection to hepatoma was investigated by studying the interrelations between hepatitis B surface antigen (HBsAg, Australia antigen) and the fast-moving 5'-nucleotide phosphodiesterase Band V isoenzyme (5'-NPDase-V) isolated from the sera of 58 patients with viral hepatitis, 34 patients with hepatoma, and 31 carriers of HBsAg. The isoenzyme was found in 34 of 37 patients who were also positive for HBsAg but in only 4 of 21 hepatitis patients who were HBsAg-negative. Five patients convalescing from hepatitis were negative for both HBsAg and the isoenzyme. Preparative gel electrophoresis showed that these two markers were different proteins. Of the 34 hepatoma patients, 29 were positive for 5'-NPDase-V. Only one isoenzyme-positive patient was positive for HBsAg by counterimmunoelectrophoresis. However, of 16 isoenzyme-positive hepatoma patients available for radioimmunoassay, 8 were HBsAg-positive. None of 21 hepatoma samples tested for antibody to HBsAg were positive. Of 21 normal carriers of HBsAg and 10 carriers with Down's syndrome, 4 persons were detected with the isoenzyme. The results suggest that HBsAg and 5'-NPDase-V in the presence of liver damage are associated, and provide a new marker enzyme between hepatitis B infection and hepatoma.

2156 CELLULAR AND HUMORAL IMMUNITY IN VIRAL HEPATITIS. (Eng.) Lee, W. M. (Columbia Univ. Coll. Physicians, Surgeons, 630 W. 168th St., New York, NY 10032). *Am. J. Clin. Pathol.* 65(5): 866-869; 1976.

The role of the immune system in viral hepatitis is discussed. Cellular and humoral immunity combine to determine the outcome following exposure to hepatitis virus and are implicated in the proposed pathogenetic mechanism for acute and chronic hepatitis. Although antibody to hepatitis B surface antigen (HB$_s$Ag) is found in virtually all patients following recovery from hepatitis B, a cell-mediated response to HB$_s$Ag can be detected in most patients during the acute phase, and it has been suggested that this may cause the acute hepatic damage by attacking virus-infected cells. Patients who have chronic active hepatitis also frequently have cell-mediated immunity to HB$_s$Ag regardless of whether the antigen can be detected in their sera; thus, previous exposure to hepatitis B may be important in initiating the disease, even in antigen-negative cases. Cell-mediated responses to liver-specific lipoprotein, a membrane antigen, occur transiently in many patients who have acute hepatitis and are persistent in virtually all with untreated chronic active hepatitis. The relative importance and precise mechanisms of these immune responses in the pathogenesis of acute and chronic hepatitis have not been determined.

2157 HEPATITIS-B SURFACE ANTIGEN AND CIRRHOSIS IN IRAQ. (Eng.) Boxall, E. H.; Flewett, T. H.; Paton, A.; Rassam, S. W. (East Birmingham Hosp., Birmingham B9 5ST, U.K.). *Gut* 17(2):119-121; 1976.

A comparison of the sensitivity of five tests--counter immunoelectrophoresis, radioimmunoassay, and three commercial hemagglutination tests (Auscell, Hepatest, and Hepanosticon)--revealed a high incidence of hepatitis-B surface antigen (HBsAg) in patients with cirrhosis. HBsAg occurred in 37 of 64 patients with cirrhosis as opposed to 3 of 91 sex- and age-matched controls. Counter immunoelectrophoresis detected about half as many positives as all other methods; radioimmunoassay was the most sensitive. The number of positive reactions in these patients from Iraq is higher than in any previously reported series of patients with cirrhosis and 7 times higher than in a normal hospital control population. However, the incidence of HBsAg in patients does not necessarily indicate that hepatitis-B virus was the cause of the disease.

2158 DIGITAL VASOSPASM AND INFARCTION ASSOCIATED WITH HEPATITIS B ANTIGENEMIA. (Eng.) Cosgriff, T. M.; Arnold, W. J. (Brooke Army Medical Center, San Antonio, TX). *JAMA* 235(13):1362-1363; 1976.

The case report of a 27-yr-old woman with hepatitis B antigenemia who had a serum sickness-like syndrome associated with digital vasospasm, striking cyanosis, and subsequent infarction of the fingertips 1 month before manifesting icteric hepatitis is presented. The patient presented with arthralgia, pain in the fingertips, and a generalized, pruritic, erythematous skin eruption. Radioimmunoassay for hepatitis B antigen was positive on five separate occasions, SGOT value was 132 μU/ml, and a liver biopsy specimen showed changes of mild viral hepatitis. A skin biopsy specimen taken from the fingertip after 48 hr of prednisone treatment showed hyperkeratosis, parakeratosis, and an intra-epidermal vesicle filled with RBC and edema fluid. Icteric hepatitis occurred 1 month later, and all symptoms were resolved after 2 weeks. Because clinical improvement was observed with prednisone therapy (60 mg/day), followed by exacerbation with steroid withdrawal and prompt improvement occurred with reinstitution of steroid therapy, inflammation may have participated in the production of the digital vasospasm.

2159 PHYTOHEMAGGLUTININ-INDUCED LYMPHOCYTE TRANSFORMATION IN LIVER DISEASES AND IN ASYMPTOMATIC HBsAg CARRIERS. (Eng.) Sato, T.; Arai, S.; Nakamura, S.; Takezawa, Y. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(1):99-100; 1976.

Phytohemagglutinin (PHA)-induced lymphocyte transformation was studied in 66 patients with liver disease or asymptomatic hepatitis B surface antigen (HBsAg) carriers. PHA-stimulated lymphocyte transformation was impaired in acute viral hepaitis. It was significantly correlated with grades f liver cell damage as shown by prothrombin time, GOT, or SGPT. It was also lower in drug-induced epatitis and in prolonged hepatitis than in con- rols. Of asymptomatic HBsAg carriers, only those ith minimal hepatic change showed lower values in stimulation index as well as incorporated radioac- ivity.

2175 CHRONIC ACTIVE HEPATITIS AS A SYSTEMIC DISEASE. (Rus.) Aprosina, Z. G.; Tareev, E. M.; Bezprozvannyi, B. K.; Potekaeva, M. A.; Traianova, T. G.; Lenchik, V. I. (I. M. Sechenov 1st Moscow Medical Inst., Moscow, USSR). *Ter. Arkh.* 47(4):127-138; 1975.

LIBRARY U. OF I.

The clinico-laboratory and morphologic characteristics of chronic active hepatitis (CAH) and its accompanying immunogenetic disorders were studied in 100 patients. The multisystemic involvement of CAH was noted in the associated abdominal pain (61%), diabetes mellitus (3%), and muscular syndromes (14%), and it was confirmed by certain laboratory findings, particularly by the marked cytopenia. Hypergammaglobulinemia greater than 2 g% was established in 93% of the patients, and it correlated with a reticuloplasmocytic bone marrow reaction in 17 of 30 patients, with plasmoreticular hyperplasia of the lymph nodes in 8 of 13 patients, and with lymphoid-plasmocytic infiltration of the liver in the majority of patients. Upon initial examination, 74 of 100 patients were diagnosed with cirrhosis of the liver. Because the morphologic picture of chronic aggressive hepatitis precedes or may coexist with the morphologic picture of liver cirrhosis, it complicated CAH diagnosis; the combination and degree of expression of clinical and laboratory symptoms seen in CAH patients also make differential diagnosis necessary. The presence of disturbances in humoral immunity in CAH was confirmed by hypergammaglobulinemia (93%), reflecting growth in the antibody level, by the rheumatoid factor in blood serum (40.3%), and by the positive test for lupus erythematous cells (51%). Systemic manifestations were observed more frequently in CAH accompanied by Australia (Au) antigen in blood serum than in the absence of Au-antigen, suggesting the role of viral injury to various organs and tissues in CAH. The cytopathic action of lymphocytes on fibroblast culture and the inhibition of leukocyte migration on Au-antigen attests to the presence of delayed hypersensitivity reactions in the pathogenesis of CAH and particularly to the state of specific delayed hypersensitivity to Au-antigen.

2176 ANTIBODY-DEPENDENT CELL-MEDIATED (K CELL) CYTOTOXICITY AGAINST ISOLATED HEPATOCYTES IN CHRONIC ACTIVE HEPATITIS.

(Eng.) Cochrane, A. M. G.; Moussouros, A.; Thomson, A. D.; Eddleston, A. L. W. F.; Williams, R. (King's Coll. Hosp., Medical Sch., London SE5 9RS, England). *Lancet* 1 (7957):441-444; 1976.

Experiments were conducted to determine whether hepatocellular damage in chronic active hepatitis is dependent upon the production of antibody to liver-specific membrane lipoprotein (LSP), rather than to autoreactive T lymphocytes. Lymphocytes from 12 of 17 patients with chronic active hepatitis were cytotoxic to isolated hepatocytes in a microcytotoxicity assay. Enriched fractions of B cells, prepared by removal of E-rosetted cells, were cytotoxic in all 12 cases, whereas T-cell fractions, prepared by removal of RBC antibody-complement-rosetted cells, were cytotoxic in only 1 case ($p<0.0005$). Hepatitis B surface antigen positive and negative cases reacted similarly. In six patients, the addition of 5 μg of aggregated immunoglobulin G significantly reduced cytotoxicity from 54% ± 15 to 13% ± 15, suggesting that K cells may be the effector cells in an antibody-dependent, cell-mediated reaction directed against liver-specific membrane lipoprotein.

2177 T CELLS AND B CELLS IN HBsAg-POSITIVE PATIENTS WITH CHRONIC PERSISTENT HEPATITIS AND ASYMPTOMATIC CARRIERS.

(Eng.) Ishimaru, H.; Ito, K.; Nakagawa, J.; Fukase, M. (Kyoto Univ. Sch. Medicine, Kyoto, Japan). *Ann. Intern. Med.* 84(4): 444-445; 1976.

The percentages of thymus- and bone marrow-derived lymphocytes (T and B cells, resp.) were determined in hepatitis B surface antigen (HBsAg)-positive patients (five of whom were asymptomatic carriers and five had chronic persistent hepatitis). The percentage of lymphocytes that formed rosettes spontaneously with sheep RBC (E rosettes, i.e., T cells) was reduced in the 5 patients with chronic hepatitis as compared with 10 normal subjects (mean, 41.6 versus 25.9). In HBsAg-positive patients with chronic persistent hepatitis, the number of E rosettes did not increase in the presence of HBsAg, nor did the reduced number of E rosettes reflect the increased numbers of B cells. The decreased number of E rosettes in the peripheral blood may reflect the diminished numbers of T cells that are associated with cellular immunity. The number of B cells in these patients was within the normal range, as were T and B cells in the five HBsAg-positive asymptomatic carriers.

2178 THE STATE OF THE KALLIKREINOGEN-KALLIKREIN SYSTEM IN PATIENTS WITH LIVER DISEASE.

(Rus.) Paskhina, T. S.; Bondar, Z. A.; Krinskaia, A. V.; Melkumova, I. S.; Polikarpova, E. G. (Inst. Biological Medical Chemistry, Moscow, USSR). *Klin. Med. (Mosk.)* 53(8):9-15; 1975.

Kallikreinogen and kallikrein levels and arginine-esterase (ethyl ester Nα-benzoyl-L-arginine) activity in the blood serum were determined in patients (aged 24-78 yr) with cirrhosis of the liver (24), fatty hepatosis changing to cirrhosis (13), and chronic hepatitis in the acute stage (6). Kallikrein activity and kallikreinogen content were measured by the original chromatographic method, based upon their separation as "cation" albumin from other trypsin-like proteinases of the blood serum and other components of the kinin system. Kallikreinogen content was lowered in all patients, particularly in those with portal and mixed cirrhosis and in those with fatty hepatosis changing to cirrhosis; kallikreinogen was 15-20% of the norm during the active phase of the disease, as compared with a level of 30-60% of the norm in patients with chronic hepatitis. Following prednisolone therapy, kallikreinogen rose to 80% of the norm in chronic hepatitis and mixed cirrhosis patients, 60% in patients with portal cirrhosis, and not more than 40% in patients with biliary cirrhosis. Free kallikrein, absent in the blood serum of healthy subjects, was found in a quantity of 10-100 Mache units (M.u.)/ml in approximately 60% of patients with an active disease course and a kallikreinogen level not below 50-60 M.u./ml. The significant variability in arginine-esterase activity, reflecting the summary activity of trypsin-like proteases in the blood serum, confirms the lack of coordination between the coagulatory, fibrinolytic, and kinin systems in liver diseases.

2179 EFFECT OF PYROGENAL ON THE INTRACELLULAR METABOLISM AND PHAGOCYTIC ACTIVITY OF LEUKOCYTES IN PATIENTS WITH CHRONIC LIVER DISEASE. (Rus.) Petrova, T. R.; Ponomareva, E. P. (Red Army Medical Inst. Kuban, Krasnodar, USSR). *Klin. Med. (Mosk.)* 53(8):34-39; 1975.

Thirty-seven patients with chronic hepatitis and 38 patients with portal and postnecrotic cirrhosis of the liver were administered pyrogenal, to determine its effect on the intracellular metabolism and phagocytic activity of leukocytes. Individualized dosages causing a 1-1.5 degree temperature increase were given i.v. on alternate days. Pyrogenal stimulated the processes of intracellular neutrophil metabolism. Elevated glycogen content in neutrophils was decreased in 63 of the patients following therapy, while increased alkaline phosphatase activity of neutrophils was further intensified, and glycolysis was strengthened. Acid phosphatase activity of neutrophils was markedly raised in the majority of patients with chronic hepatitis, and it was moderately raised in patients with cirrhosis. Therapy significantly raised the level of nucleic acids in neutrophils ($p<0.001$) in 69 of the patients. In these patients, decreased total content of albumin was accompanied by low phagocytic intensity. The data indicate that pyrogenal positively affects the functional activity of leukocytes.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

2184 DETERMINANTS OF DERANGED SODIUM AND WATER HOMEOSTASIS IN DECOMPENSATED CIRRHOSIS. (Eng.) Epstein, M.; Pins, D. S.; Schneider, N.; Levinson, R. (Veterans Admin. Hosp., 1201 N.W. 16 St. Miami, FL 33125). *J. Lab. Clin. Med.* 87(5): 822-839; 1976.

Mechanism(s) responsible for the abnormalities of renal sodium and water handling in advanced alcoholic liver disease were investigated in 13 patients (aged 37-54 yr) who were housed in an environmentally controlled metabolic ward at constant temperature. Each patient consumed a daily diet of 10 mEq sodium, 100 mEq potassium, and 800-1,000 ml water. All patients underwent a contol study followed, 2-3 days later, by immersion in water to the neck level. Subsequently, patients underwent additional control and immersion studies following chronic spironolactone therapy (100-400 mg/day) for a minimum of 5 days. Immersion resulted in a marked natriuresis and kaliuresis in the majority of patients with decompensated Laennec's cirrhosis and avid renal sodium retention. The marked increase in sodium excretion during immersion plus spironolactone administration, as compared to the modest increase in sodium excretion after spironolactone administration alone, indicates that the major component of the natriuresis is secondary to enhanced distal delivery of filtrate. This is supported by a concomitant kaliuresis and an increase in free H_2O clearance. These findings support the concept that the pre-existing sodium-retaining state was secondary to decreased distal delivery, and that hyperaldosteronism was a permissive factor. Immersion induced a sustained increase in central blood volume in the absence of infusion exogenous volume expanders, supporting the theory that the abnormal sodium retention in cirrhosis is mediated by some parameters of diminished effective blood volume. Immersion was also capable of inducing a prompt and remarkable "normalization" of creatinine clearance in a majority of patients with diminished creatinine clearance, suggesting that immersion may reverse the elevated renal vascular tone in cirrhosis.

2185 HEPATIC COLLAGEN PROLINE HYDROXYLASE ACTIVITY IN ALCOHOLIC LIVER DISEASE. (Eng.) Mezey, E.; Potter, J. J.; Maddrey, W. C. (Baltimore City Hosp., 4940 Eastern Ave., Baltimore, MD 21224). *Clin. Chim. Acta* 68(3):313-320; 1976.

The activity of hepatic collagen proline hydroxylase was examined in biopsy samples as a factor in collagen synthesis in 77 patients with alcoholic liver disease. Patients with alcoholic hepatitis (47) had the highest mean activity of hepatic collagen proline hydroxylase, while the activity of the enzyme was markedly increased in patients with nonspecific changes (6) on liver biopsy. In patients with fatty infiltration of the liver (17), the enzyme activity was increased to above normal only when expressed per mg of protein. The patients with alcoholic hepatitis and inactive cirrhosis showed significant elevations in the urinary excretion of peptide bound hydroxyproline, as compared to normals. Follow-up determinations in 16 patients revealed a decrease in the enzyme activity but no change in urinary hydroxyproline. The decrease in the mean enzyme activity was not related to histologic changes or to prednisolone (40 mg/day) therapy. These findings are consistent with the clinical observation that alcoholic hepatitis often progresses to cirrhosis.

2186 LIVER DISEASE--A PROMINENT CAUSE OF SERUM IgE ELEVATION. (Eng.) Van Epps, E.; Husby, G.; Williams, R. C., Jr.; Strickland, R. G. (Univ. New Mexico, Sch. Medicine, Albuquerque, NM 87131). *Clin. Exp. Immunol.* 23(3):444-450; 1976.

Using radioimmunoassay, serum IgE concentrations were found to be elevated in 37 out of 67 patients with acute or chronic liver disease of differing etiology. In these patients, the mean IgE concentrations showed an eight-fold increase above that observed in control subjects. In patients with liver disease, increased IgE levels occurred in the absence of eosinophilia, clinical evidence of atopy, or other known causes of IgE elevation. No IgE-containing plasma cells were detected in the liver biopsies from 32 patients. Peripheral blood T cells were significantly decreased from normal in the patients with liver disease, but no correlation emerged between serum IgE levels and absolute peripheral blood T-cell numbers. These findings emphasize the importance of liver disease as a significant cause of serum IgE elevation.

2187 A CONTROLLED STUDY OF THERAPEUTIC PORTACAVAL SHUNT IN ALCOHOLIC CIRRHOSIS. (Eng.) Rueff, B.; Prandi, D.; Degos, F.; Sicot, J.; Degos, J. D.; Sicot, C.; Maillard, J. N.; Fauvert, R.; Benhamou, J. P. (Hopital Beaujon, 922110 Clichy, France). *Lancet* 1(7961):655-659; 1976.

A controlled study of therapeutic end-to-side portacaval shunt was carried out in 89 patients with alcoholic cirrhosis. Significantly fewer patients with the shunt had recurrent bleeding; 6 out of 25 developed gastrointestinal bleeding in comparison with 36 of 49 patients who did not have the operation ($p < 0.001$). Chronic hepatic encephalopathy was more common in the shunt group (6 of 24) than in the control group (0 of 36, $p < 0.001$). The survival rate was lower, but not significantly, in patients with shunts. No overall benefit of the operation was demonstrated in cirrhotic patients, using the selection criteria and the type of surgical shunt in this study.

LIVER AND BILIARY TRACT

Cirrhosis

2195 DIAGNOSIS OF CIRRHOSIS AND HEPATITIS BY QUANTITATIVE HEPATIC AND OTHER RETICULOENDOTHELIAL CLEARANCE RATES. (Eng.) DeNardo, S. J.; Bell, G. B.; DeNardo, G. L.; Carretta, R. F.; Scheibe, P. O.; Imperato, T. J.; Jackson, P. E. (Univ. California Sch. Medicine, Sacramento, CA 95817). *J. Nucl. Med.* 17(6):449-459; 1976.

A kinetic radionuclide technique for quantitative assessment of colloid clearance rate constants for the liver, spleen, and other reticuloendothelial (RE) tissues is described. The technique was used to differentiate cirrhosis, fatty metamorphosis, hepatitis, and normal function in 22 patients by utilizing ^{198}Au-colloid, *in vivo* organ counting, and kinetic computer modeling to provide a quantitative assessment of clearance rate constants. The actual plasma clearance rates were determined by substituting blood volume for plasma volume. In normal subjects, the mean clearance rate constants for the liver, spleen, and extra hepatosplenic reticuloendothelial system were 16.0, 1.4, and 3.4 ml/min/100 ml of plasma, resp. The mean hepatic clearance rate constant was normal in hepatitis (16.8 ml/min/100 ml), reduced in cirrhosis (5.7), and slightly reduced in fatty metamorphosis (10.4). Both the hepatic to splenic and the hepatic to extrahepatosplenic ratios of clearance rate constants were reduced in cirrhosis (3.9 and 0.8) and were slightly reduced in fatty metamorphosis (11.9 and 2.6) and hepatitis (13.9 and 3.3). The splenic clearance rate constants were normal in these three diseases. It is concluded that this method compares well with clearance blood flow results reported by other investigators using other techniques.

2196 PERCUTANEOUS HAM-SPLENOPORTOSCINTIGRAPHY, PORTA-SYSTEMIC SHUNTING AND HEPATIC SINUSOIDAL PRESSURE IN CIRRHOSIS OF THE LIVER. (Eng.) Weits, J.; Gips, C. H.; Beekhuis, H.; Kruizinga, K.; Niermeijer, P.; Piers, D. A. (Univ. Hosp., The Netherlands). *Neth. J. Med.* 18(5):176-183; 1975.

Percutaneous splenoportoscintigraphy (SPS), using ^{99m}Tc-human albumin microspheres (HAM), was performed in patients with liver cirrhosis, and the results were compared with parameters of portal pressure and porta-systemic (p-s) shunting. HAM were injected percutaneously into the spleen as a small bolus using a short thin needle. HAM-SPS was successfully performed in 36 of 38 patients, with no complications. Pulmonary imaging indicating p-s shunting was found in 17 patients. There was a positive correlation ($p = 0.02$) between pulmonary imaging and an abnormal rectal arterial ammonia test. Pulmonary imaging as well as delayed visualization of the liver were associated ($p = 0.001$ and $p < 0.01$, resp.) with a hepatic sinusoidal pressure greater than or equal to 8 mm Hg (marked portal hypertension). Hepatic sinusoidal pressure increased with increasing spleen-lung interval. Pulmonary imaging did not correlate with the presence or absence of esophageal varices, with vertebral column imaging on i.v. ^{99m}Tc-colloid scintigraphy (conventional liver scintigraphy), or with distension of portal venous tributaries, as observed during peritoneoscopy. It is concluded that SPS be recommended in those cases where information is desired on the portal venous system, on the presence or absence of porta-systemic shunts, and on the probability of marked portal hypertension.

2197 INCOMPLETE MEMBRANOUS OBSTRUCTION OF THE INFERIOR VENA CAVA: HEMODYNAMIC MEASUREMENTS AND CORRECTION BY BALLOON MEMBRANOTOMY AND SURGICAL RESECTION. (Eng.) Horisawa, M.; Yokoyama, T.; Juttner, H.; Reynolds, T. B. (Nagoya Univ. Sch. Medicine, Nagoya, Japan). *Arch. Surg.* 111(5):599-602; 1976.

The case of a 38-yr-old man with rare membranous obstruction of the inferior vena cava (IVC) at the level of the diaphragm is described. The patient had chronic liver disease and portal hypertension, initially thought to be caused by secondary biliary cirrhosis, because of a history of long-term infestation with *Clonorchis sinensis*, or by chronic active viral hepatitis, because of a positive hepatitis B surface antigen test and a history of blood transfusion. At the time of hemodynamic evaluation of portal hypertension with hepatic vein catheterization, typical membranous obstruction of the IVC was discovered and thought to be the cause of the liver disease. The obstruction was thin and incomplete, and was corrected by balloon membranotomy and surgical resection. Hepatic vein catheterization in patients with chronic liver disease and portal hypertension allows detection of this lesion as well as evaluation of hepatic and portal hemodynamics.

2198 NORMAL SERUM GASTRIN LEVELS IN PATIENTS WITH LIVER CIRRHOSIS. (Eng.) Pointner, H. (Medizinische Universitatsklinik, Lazarettgasse 14, A-1097, Wien, Austria). *Digestion* 13(6):372-374; 1975.

Serum gastrin concentrations were determined radioimmunologically after an overnight fast in 28 patients with histologically confirmed liver cirrhosis. Mean value and standard deviation in the patients with cirrhosis (30.1 ± 19.3 pg/ml) was not significantly different from the mean value established in 275 normal subjects (39.7 ± 21.3 pg/ml). It seems doubtful that the very small gastrin elevation previously reported in cirrhotic patients is responsible for the increased incidence of ulcers seen in patients with liver cirrhosis.

2199 FAMILIAL CIRRHOSIS OF VIRAL ETIOLOGY. (Rus.) Iurkovskaia, N. B. (Hosp. Infectious Diseases No. 5, Kiev, USSR). *Klin. Med. (Mosk.)* 53(8):141-143; 1975.

The death of 5 children in a family from cirrhosis of the liver accompanied by splenomegaly, within a 23-yr period, indicated a familial disease of viral etiology. Botkin's disease was diagnosed in two cases. Family pathology also included a pair of premature twins who died within several days of birth, a 1-month-old child who died from meningitis, and a 2-yr-old child who died from pneumonia. The father suffered from disseminated pulmonary tuberculosis and duodenal ulcer disease; cirrhosis was diagnosed subsequently on the basis of jaundice, and death occurred 2 yr later. Cirrhosis that follows Botkin's disease frequently retains its infectious nature, as characterized by intrafamilial epidemic hepatitis and subsequent cirrhosis.

2200 AUTOIMMUNE FACTORS IN AFRICAN CIRRHOSIS. CORRELATION WITH HEPATITIS B SURFACE ANTIGEN AND ANTIBODY. (Eng.) Sadikali, F.; Doniach, D. (Makerere Univ. Medical Sch., Kampala, Uganda). *Am. J. Gastroenterol.* 64(6):484-489; 1975.

Sera were tested for autoantibodies in 98 patients in Uganda with cryptogenic cirrhosis, and the results were correlated with serological tests for hepatitis B surface antigen (HBsAg) and antibody to HBsAg (HBsAb). Smooth muscle antibodies (SMA) were detected in 23 of the patients, but there was no difference in the incidence of SMA between HBsAg-positive and negative cases. Antinuclear antibodies (ANA) were detected in five cases; mitochondrial, gastric, and thyroid antibodies were not found in any patient. Unlike other geographical locations, autoimmune mechanisms appear to play little part in the progression of chronic liver disease in Africans from Uganda. Hepatitis B surface antigen was present in 36 and HBsAb was present in 47 of the patients. Although evidence for past exposure to hepatitis B virus (as shown by detection of HBsAb) was present in at least 30 out of the 62 HBsAg-negative cases, there was no greater incidence of autoantibodies in HBsAg-negative patients with or without HBsAb. Persistent infection with hepatitis B virus and continuing liver damage may be an important factor, but these results do not suggest that the virus plays a role in the etiology of chronic liver disease by triggering an autoimmune reaction.

2201 INCREASED URINARY EXCRETION OF L-XYLULOSE IN PATIENTS WITH LIVER CIRRHOSIS. (Eng.) Oka, H.; Suzuki, S.; Suzuki, H.; Oda, T. (Univ. Tokyo, Faculty Medicine, Bunkyo-ku, Tokyo, Japan). *Clin. Chim. Acta* 67(2):131-136; 1976.

The urinary excretions of L-xylulose, xylitol, and D-glucarate after the p.o. administration of glucuronolactone (5 g) were measured in 14 healthy persons, 8 patients with diabetes mellitus, 9 patients with acute hepatitis in recovery stage, 10 patients with chronic hepatitis, and 14 patients with liver cirrhosis. In normal subjects, the mean value of L-xylulose excretion, measured by an enzymatic method, was 14.6 μmol/2 hr with a range from 6.5 to 21.8. Marked increase of L-xylulose excretion was observed in cirrhotic patients; the mean value was 97.1 ± 19.8, with a range from 22.0 to 236.6. Though some cases of acute and chronic hepatitis showed higher values than the normal range, no case exceeded 50 μmol/2 hr. The urinary excretion of xylitol, assayed by gas chromatography, in cirrhotic patients was also higher than normal, and no increase was observed in D-glucarate excretion. The values of L-xylulose excretion in cirrhosis were correlated with the values of serum total bilirubin (r=0.88), albumin (r=-0.73), albumin/globulin ratio (r=-0.69), lactate dehydrogenase (r=0.91), and prothrombin time (r=0.73). These findings indicate that the measurement of L-xylulose in urine after p.o. glucuronolactone loading provides a useful tool for evaluating the severity of liver cirrhosis.

2202 HYPOTHALAMIC-PITUITARY-GONADAL FUNCTION IN MEN WITH CIRRHOSIS OF THE LIVER. (Eng.) Mowat, N. A. G.; Edwards, C. R. W.; Fisher, C. R.; McNeilly, A. S.; Green, J. R. B.; Dawson, A. M. (Woodend General Hosp., Aberdeen, U.K.). *Gut* 17(5):345-350; 1976.

Hypothalamic-pituitary-gonadal function was studied in 37 cirrhotic men, 25 of whom were alcoholic. In

ddition to the measurement of hormone concentra-
ions under basal conditions, hormone responses to
ynamic tests of hypothalamic-pituitary-gonadal
unction were also assessed. Irrespective of
tiology, cirrhotic patients had significantly
educed free testosterone concentrations. Despite
ow free testosterone concentrations and reduced
r absent spermatogenesis, basal levels of lu-
einizing hormone (LH) and follicle stimulating
ormone (FSH) were normal in nearly all patients,
uggesting impaired function of the hypothalamic-
ituitary-gonadal axis. In 14 cirrhotic men, 7 of
hom had gynecomastia, the ability of the pituitary
o secrete LH and FSH in response to exogenous
onadotrophin releasing-hormone (LH/FSH-RH) was
ssessed. A normal LH response to LH/FSH-RH was
btained in patients without gynecomastia. An
xaggerated LH response was found in four of seven
ith gynecomastia, suggesting Leydig cell failure..
The Leydig cell response to exogenous gonadotrophin
in eight consecutive cirrhotic patients was prob-
ably abnormal but difficult to interpret, as all
but one were within conventionally accepted limits
of normality. The patients without gynecomastia
gave a normal or minimally exaggerated FSH response
to LH/FSH-RH. Six of seven with gynecomastia gave
a markedly exaggerated response, suggesting failure
of spermatogenesis, and all tested were either
azoospermic or oligospermic. The single patient with
a normal FSH response had a normal sperm count.
Therefore, the pituitary cells response to LH/FSH-
RH, and the Leydig cells of the testes show response
to exogenous gonadotrophin.

2203 *Pasteurella multocida* PERITONITIS IN HEPATIC CIRRHOSIS WITH ASCITES.

(Eng.) Gerding, D. N.; Khan, M. Y.; Ewing, J. W.; Hall, W. H. (Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *Gastroenterology* 70(3):413-415; 1976.

Cases of *Pasteurella multocida* peritonitis in association with cirrhosis and ascites are described in two men, aged 51 and 62 yr. Both patients had close contact with domestic animals, but neither had been bitten. *P. multocida* was the only organism isolated from the ascitic fluid in both patients. Despite treatment with oxygen, albumin, and plasma, the second patient died within hours of admission. The first patient recovered from peritonitis after treatment with clindamycin and gentamicin, but he died after developing increased hepatic and renal failure. Autopsy revealed no bowel perforations; micronodular cirrhosis, fatty metamorphosis, and alcoholic hepatitis were observed in the liver. *P. multocida* should be considered as a possible cause of peritonitis in cirrhotic patients with a history of close contact with animals, particularly cats. It is suggested that when *P. multocida* infection is suspected, empiric antibiotic selection should include penicillin G because of its proven efficacy and low toxicity.

2204 SPLANCHNIC HEMODYNAMICS IN CIRRHOTIC PATIENTS WITH ESOPHAGEAL VARICES AND GASTROINTESTINAL BLEEDING.

(Eng.) Lebrec, D.; Kotelanski, B.; Cohn, J. N. (Unite de Recherches de Physio-Pathologie Hepatique (INSERM), Hopital Beujon, 92110 Clichy, France). *Gastroenterology* 70(6):1108-1111; 1976.

The relation between hemodynamics and portal hypertension was investigated in 20 cirrhotic patients with esophageal varices and gastrointestinal bleeding within the previous week. The patients underwent hemodynamic studies, using an indicator dilution technique based upon selective catheterization of the splanchnic arteries and hepatic vein. Portasystemic shunting of splenic arterial flow was accomplished in 16 of 20 patients (78%). Two of three patients whose bleeding was not due to varices had no detectable shunting of splenic inflow, and in the third, a 25% shunt was detected. Systemic shunting of superior mesenteric arterial flow was more variable and averaged 59% for the entire group. In 25%, mesenteric shunting was essentially complete, but in the other 15 patients varying fractions (10-100%) of mesenteric flow continued to perfuse the liver. No shunting was detected in three patients with nonvariceal bleeding. There was no correlation between the severity of the portal hypertension, as assessed from the pressure gradient, and the fraction of mesenteric flow passing through the portasystemic collateral circulation. Hepatic blood flow also varied. Arteriovenous oxygen difference across the liver averaged 3.4 ml/100 ml. Hepatic venous oxygen content was not related to the percentage of portasystemic shunting. All patients had cardiac indices over 3.4 $l/min/m^2$. These data indicate the variability of the splanchnic hemodynamic pattern that may exist in alcoholic patients with esophageal varices. If hemodynamic factors are important in determining the response to surgery, indicator dilution studies to quantitate portasystemic shunting may be a vital part of preoperative evaluation.

2205 LITHOCHOLATE METABOLISM DURING CHENOTHERAPY FOR GALLSTONE DISSOLUTION. 2. ABSORPTION AND SULPHATION.

(Eng.) Allan, R. N.; Thistle, J. L.; Hofmann, A. F. (Dept. Medicine, Birmingham Univ., Birmingham, England). *Gut* 17(6):413-419; 1976.

The amount of lithocholate input and the size of the total lithocholate exchangeable pool were measured using isotope dilution in three patients who ingested chenodeoxycholic acid (mean dose 11.0 mg/kg/day, minimum of 6 months) for gallstone dissolution and in two healthy control subjects. Because the specific activity decay curve was biexponential in appearance, input was calculated using a stochastic analysis employing the Stewart-Hamilton equation. By this method, the lithocholate input and the size of the exchangeable pool in gallstone patients during chenic acid ingestion was four to five times that observed in the healthy control subjects. It was calculated that about one-fifth of the newly formed

LIBRARY U. S. ...

lithocholate was absorbed in both gallstone patients and healthy control subjects. The extent of sulfation of absorbed lithocholate was then measured in seven gallstone patients who had been ingesting chenodeoxycholic acid for gallstone dissolution. This was accomplished by defining the chemical form of radioactivity in bile after i.v. administration of labeled lithocholate. Similar studies were carried out in eight healthy control subjects, but, in addition, the extent of sulfation of injected lithocholylglycine and lithocholyltaurine was also defined. When lithocholate was injected, the majority of radioactivity in bile (50-60%) was present as sulfated conjugates, both in gallstone patients and in healthy control subjects. The degree of sulfation was greater for glycine than taurine conjugates; these findings, suggesting preferential sulfation of the glycine conjugates of lithocholate, were confirmed by showing that injected lithocholylglycine was sulfated to a much greater extent than injected lithocholyltaurine. The results indicate that in patients receiving chenic acid, there is effective sulfation of lithocholate, especially its glycine conjugates, despite a considerable increase in lithocholate absorption; they may provide an explanation for the lack of hepatotoxicity of chenic acid in man.

2206 SPONTANEOUS BACTERIAL EMPYEMA IN CIRRHOSIS.

(Eng.) Flaum, M. A. (Veterans Admin. Hosp., West Haven, CT). *Gastroenterology* 70(3): 416-417; 1976.

A case of spontaneous bacterial empyema occurring in a 48-yr-old man with cirrhosis and long-standing pleural effusion is reported. The patient presented with jaundice, hepatomegaly, ascites, and massive right pleural effusion 1 yr before the bacterial empyema was encountered. At that time, thoracentesis yielded sterile fluid with a high number of WBC; 1 yr later, thoracentesis yielded purulent fluid, which, when cultured, yielded *Escherichia coli*. Cultures of ascitic fluid and blood were sterile. A left pleural effusion developed, and it yielded results similar to those of the right effusion. Cultures of pleural fluid became sterile following large doses of ampicillin and tube thoracostomy drainage, but the patient died after the development of portalsystemic encephalopathy and gastrointestinal bleeding. Autopsy showed advanced micronodular cirrhosis with hepatosplenomegaly and ascites. This case suggests that transudates other than ascites can be infected in a manner similar to ascites.

2207 ABNORMAL VITAMIN D METABOLISM IN PATIENTS WITH CIRRHOSIS.

(Eng.) Hepner, G. W.; Roginsky, M.; Moo, H. F. (Harbor General Hosp., Torrance, CA 90509). *Am. J. Dig. Dis.* 21(7):527-532; 1976.

To assess the role of hepatic function and alcohol on vitamin D metabolism, serum 25-hydroxyvitamin D (25-OHD) levels were measured in 20 healthy nonalcoholic control subjects, 31 "inactive" cirrhotics whose alcoholism was in remission, 8 alcoholic cirrhotics, and 15 alcoholics with normal liver function. Cirrhosis, but not alcoholism, was associated with low serum 25-OHD levels. The aminopyrine breath test (ABT) was performed because aminopyrine, like vitamin D_3, is metabolized by hepatic microsomes; the ABT correlated highly ($p<0.01$) with serum 25-OHD in the inactive cirrhotics. After an i.v. injection of 120 μg vitamin D_3, serum 25-OHD rose significantly within 24 hr in healthy controls and two patients with celiac disease but not in six inactive cirrhotics. These data suggest that impaired 25-hydroxylation of vitamin D in patients with cirrhosis is related to the degree of hepatic dysfunction.

2208 REVERSIBILITY OF SEVERE HEPATIC DAMAGE CAUSED BY JEJUNOILEAL BYPASS AFTER RE-ESTABLISHMENT OF NORMAL INTESTINAL CONTINUITY.

(Eng.) Soyer, M. T.; Ceballos, R.; Aldrete, J. S. (Sch. Medicine, Univ. Alabama, Birmingham, AL). *Surgery* 79(5):601-604; 1976.

The case of a 24-yr-old woman who underwent a jejunoileal bypass operation and developed severe hepatic damage is presented. The damage was reversed after re-establishment of the normal intestinal continuity. Following the initial bypass operation, the patient developed jaundice and abnormal liver function tests. A needle biopsy of the liver, 1 yr after the bypass, revealed severe hepatic cirrhosis. The normal intestinal continuity was subsequently restored, and cholecystectomy, appendectomy, and excision of a benign ovarian cyst were performed during the same operation. The patient's liver function tests returned to normal. When surgery was again performed 8 months later, to repair the incarceration of several loops of intestine in an incisional hernia, the liver showed only minimal residual abnormalities.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

2220 CLINICO-ROENTGENOLOGICAL EVALUATION OF NEGATIVE CHOLECYSTOGRAPHY. (Rus.) Ginsburg, S. N.; Kagan, Iu. L. (N. A. Semashko Moscow Medical Stomatologic Inst., Moscow, USSR). *Vestn. Rentgenol. Radiol.* (2):58-62; 1975.

Infusion cholegraphy was performed in 205 patients with negative cholecystography. The gallbladder contrast range was absent in 128 patients during both procedures. In three of these cases, the contrast range was absent simultaneously in the gallbladder and the bile ducts. In 125 of these cases, obliteration or detachment of the gallbladder was diagnosed. The gallbladder contrast range was insufficient for diagnosis in 11 of the 205 patients and it was sufficient in 66 patients. All patients who underwent surgery had pathologic changes causing negative cholecystography: calculus cholecystitis was found in 107 of 109 patients, and phlegmonous cholecystitis without calculus was found in 2 of the 109 patients. Negative cholecystography was almost always (96.5%) caused by cholelithiasis and its accompanying organic changes at the bladder neck and duct.

2221 REFLUX CHOLANGIOGRAPHY IN SPHINCTEROPLASTY OR ENTEROBILIARY ANASTOMOSIS. (Eng.) Bilbao, M. K.; Dotter, C. T. (Univ. Oregon Medical Sch., Portland, OR 97201). *Radiology* 115(2):585-588; 1975.

The effectiveness of reflux cholangiography, a simple modification of hypotonic duodenography, was evaluated in five patients with sphincteroplasties and in four patients with enterobiliary anastomoses. The procedure involved rapid, controllable duodenal intubation, drug-induced paralysis, distension with a contrast agent, and radiography after gravity-induced reflux through the fistula. Satisfactory demonstration of the hypotonic duodenum and the enterobiliary anastomosis was achieved in all cases. The authors conclude that in patients with abnormal enterobiliary communications, this method is effective for demonstrating not only biliary and pancreatic ducts, but also fistulas, the duodenum, and the papilla of Vater. The technique is uncomplicated and is suitable for the serial study of chronic conditions. In addition, it is useful for surgical evaluation as a preliminary to more complex procedures and enhances the value of endoscopic retrograde cholangiopancreatography.

2222 VALUE OF GALLBLADDER B-SCAN ULTRASONOGRAPHY.

(Eng.) Tabrisky, J.; Lindstrom, R. R.; Herman, M. W.; Castagna, J.; Sarti, D. (Harbor General Hosp., 1000 West Carson St., Torrance, CA 90509). *Gastroenterology* 68(5):1246-1252; 1975.

The usefulness of gallbladder B-scan ultrasonography was evaluated in 20 patients who had a poor or nonvisualization of the gallbladder after a cholecystogram, sufficiently abnormal liver chemistries to render conventional radiography futile, and a precarious clinical condition requiring emergency laparotomy. Eleven patients demonstrated a normal scan with smooth walls and clear sonolucency; there were 5 false negatives in this group; 3 of them were caused by small stones (under 8 mm). Two patients in the group had alcoholic hepatitis and two had impeded iopanoic acid absorption causing nonvisualization. Four patients showed no identifiable sonolucency in the gallbladder region; all had large numbers of stones. Five patients showed an irregular wall and/or internal echoes. Patients in this group had gangrenous and nongangrenous cholecystitis, hydrops of the gallbladder, malignant neoplasm, and cholelithiasis. It is concluded that the B-scan can be a valuable test for confirming the significance of a radiographically nonvisualized gallbladder or for detecting a biliary tract lesion in a condition that precludes conventional radiographic visualization.

2223 BILE PERITONITIS IN ACUTE CHOLECYSTITIS.

(Eng.) Dale, G.; Solheim, K. (Ulleval Hosp., Oslo, Norway). *Acta Chir. Scand.* 141(8): 746-748; 1975.

Three cases of bile peritonitis in acute cholecystitis are presented, and a further 17 cases, occurring over a 15-yr period, are reviewed. Because x-ray examination was of little diagnostic use, the correct diagnosis was suggested preoperatively in only nine cases. The fundus of the gallbladder was the most frequent site of perforation, although in one case the bile seemed to escape through the inflamed gallbladder wall. There was no specific symptom in any of the cases of gallbladder perforation, although most patients had signs of generalized peritonitis. The patients were an average of 72 yr old and represented 1.8% of 1,123 patients with acute cholecystitis admitted during the 15-yr period. Three patients did not undergo surgery, and all died. Mortality with cholecystostomy was 4 of 11, with cholecystectomy it was 1 of 4, and with cholecystectomy and exploration of common duct it was 0 of 2. It is recommended that early operative treatment of acute cholecystitis be chosen whenever possible.

2224 LITHOCHOLATE METABOLISM DURING CHENOTHERAPY FOR GALLSTONE DISSOLUTION. 1. SERUM LEVELS OF SULPHATED AND UNSULPHATED LITHOCHOLATES.

(Eng.) Allan, R. N.; Thistle, J. L.; Hofmann, A. F.; Carter, J. A.; Yu, P. Y. S. (Dept. Medicine, Birmingham Univ., Birmingham, England). *Gut* 17(6):405-412; 1976.

Serum levels of total sulfated and total unsulfated lithocholates were each measured by a specific radioimmunoassay in 66 patients who ingested chenodeoxycholic (chenic) acid (mean dose, 13 ± 6 mg/kg/day; range, 6-25 mg/kg/day, 12 months) for gallstone dissolution and in 35 gallstone patients who ingeste either cholic acid or placebo. No changes occurred in serum lithocholate levels in the control groups. In patients ingesting chenic acid, there was a twofold increase in serum levels of total lithocholate, but the percent sulfation (>75%) remained unchanged during chenotherapy. There was no correlation in the chenic acid-treated group between serum lithocholate levels and the proportion of lithocholate in biliary bile acids or changes in serum SGOT. The data suggest that there is effective sulfation of lithocholate in such patients; this may explain the lack of hepatotoxicity observed during ingestion of chenic acid.

2225 DIURNAL CHANGES OF BILE LIPID CONCENTRATION IN HEPATIC BILE OF CHOLECYSTECTOMIZED MAN.

(Eng.) Gerolami, A.; Crotte, C.; Reynier, M. O.; Mule, A.; Domingo, N.; Sarles, H. (Unite de Recherches de Pathologie digestive, Inserm, 46, chemin de la Gaye, F-13009 Marseille, France). *Digestion* 12(4-6):209-220; 1975.

Diurnal variations of bile lipid concentration were studied in 10 patients with a T tube in the main bil duct following a cholecystectomy. Five or 6 bile sa ples were collected every 24 hr from each patient during 3-40 days. The enterohepatic cycle was not significantly modified because total bile samples did not exceed 40 ml/day. Significant diurnal variations were observed in cholesterol concentration. Changes in lecithin concentration seemed to be similar in seven patients but they did not reach the level of significance in any individual patient. Maximal values were observed between 4 and 8 a.m. and minimal values at 4 p.m. Bile salt concentration varied without any circadian periodicity. The patients with highest cholesterol concentrations also had the highest mean lecithin concentration. There was little variation in bile salt concentration from one patient to another. It is concluded that individual and circadian variations of bile lipids can modify the bile saturation in cholesterl by parallel changes of lecithin and cholesterol oncentration, without corresponding changes in bile alt concentration.

226 CHOLELITHIASIS IN CHILDREN. (Eng.) Harned, R. K.; Babbitt, D. P. (Univ. ebraska Sch. Medicine, Omaha, NB). *Pediatr. adiol.* 117(2):391-393; 1975.

he association of cholelithiasis with hemolytic nemia in children was reviewed in 367 cases. emolytic disease was associated with the cholelithiasis in 69 cases; sickle cell disease and pherocytosis were the most common types. Oral holecystograms were diagnostic in about 70% of he cases, and plain film studies were also of iagnostic value as 56 of 110 patients had gallstones isible on plain radiographs of the abdomen. The esults show that cholelithiasis is more common in hildren without hemolytic disease than in those with emolytic anemia.

2227 PENETRATION OF CLINDAMYCIN PHOSPHATE INTO THE ABNORMAL HUMAN BILIARY TRACT. (Eng.) Brown, R. B.; Martyak, S. N.; Marza, M.; Curtis, L.; Weinstein, L. (Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA 02115). *Ann. Intern. Med.* 84(2):168-170; 1976.

Following the i.v. administration of clindamycin (600 mg) in 14 patients undergoing biliary tract surgery (37 with complete obstruction of the common bile duct), concentrations of the drug were measured in gallbladder and common bile duct, gallbladder wall, liver, and serum. Patients with patent common ducts had high levels of active drug at all hepatobiliary sites; concentrations were 2.5-3 times higher in bile and liver than in serum. Persons with obstruction of the common duct had no measurable drug in bile and had reduced levels in gallbladder wall; however, concentrations in the liver were slightly higher than those in the group without obstruction. The results suggest that, even in the presence of common duct obstruction, the concentrations of active clindamycin in the liver may be sufficient to limit the spread of intrahepatic infections due to susceptible organisms.

GENERAL

2253 GASTRIN CONTENT AND GASTRIN RELEASE: STUDIES ON THE ANTRAL CONTENT OF GASTRIN AND ITS RELEASE TO SERUM DURING STIMULATION BY FOOD. (Eng.) Malmstrom, J.; Stadil, F. (Rigshospitalet, 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):71-76; 1976.

The antral and serum gastrin concentrations were studied in eight patients with various gastrointestinal diseases during a 30-min intragastric instillation of meat extract (bovril). Bovril caused a steady increase in serum concentrations of gastrin and an acute fall in the antral content of gastrin to 42 ± 8.4% during the first 10 min. After 10 min, the antral content increased again to the basal values. No change in gastrin components was detected; component III (gastrin-17) constituted over 95% of the antral gastrins throughout the 30-min period. The serum gastrin response to a steak meal was higher in 22 duodenal ulcer patients than in 9 normal subjects, and it was higher postoperatively in 8 patients who were studied before and after truncal vagotomy. In the duodenal ulcer patients with the highest antral content of gastrin, the serum response to food was higher only during the early phase of the feeding response. It is concluded that the gastrin content of the antral mucosa represents an acute releasable pool of gastrin-17, which contributes only to the first 10-15 min of the feeding response. It does not reflect the total amount of gastrin released into the circulation during feeding.

2254 SUCCESSFUL TREATMENT OF A MALIGNANT GASTRINOMA WITH STREPTOZOTOCIN.

(Eng.) Hayes, J. R.; O'Connell, N.; O'Neill, T.; Fennelly, J. J.; Weir, D. G. (Sir Patrick Duns Hosp., Dublin, Ireland). *Gut* 17(4):285-288; 1976.

The treatment of a 36-yr-old woman with metastatic gastrinoma with streptozotocin is described. Two courses of i.v. streptozotocin showed no effect (two doses of 0.8 g and two doses of 1.6 g, separated by 7 days; four doses of 2 g, each separated by 7 days). However, 3 months after two doses of 4 g streptozotocin were given into the celiac axis, there was a marked reduction in hepatic size and a fall in fasting plasma gastrin levels from 1,430 pmol/l to 240 pmol/l. Seven months after treatment, fasting plasma gastrin levels were 125 pmol/l. Three years after treatment, the patient remains well. This treatment may be valuable in the management of the metastatic complications of malignant gastrinoma.

2255 EFFECT OF EPINEPHRINE AND NOREPINEPHRINE ON GASTRIN RELEASE AND GASTRIC SECRETION OF ACID IN MAN.

(Eng.) Christensen, K. C.; Stadil, F. (Rigshospitalet, 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):87-92; 1976.

The physiological importance of epinephrine and norepinephrine for gastrin release and gastric secretion of acid was studied in 49 patients with duodenal ulcer or with normal stomach and duodenum. Twenty patients received 5 ng/kg/min epinephrine i.v. over 1 hr; 18 patients received 50 ng/kg/min, and norepinephrine was given to the remaining 11 patients, who received both 5 and 50 ng/kg/min. The low dose of epinephrine stimulated gastrin release and acid secretion, whereas the high dose stimulated the gastrin release but did not change acid secretion. Norepinephrine in the low dose caused a very small increase in gastrin release and no change in acid secretion, whereas the high dose inhibited acid secretion without any change in gastrin concentration. No postoperative change was observed in the release of gastrin by both doses of epinephrine after truncal vagotomy in six and seven patients with duodenal ulcer. It is concluded that both epinephrine and norepinephrine may be of importance in the physiological regulation of gastrin release and gastric acid secretion.

2256 CLINICAL RESPONSE OF DERMATITIS HERPETIFORMIS SKIN LESIONS TO GLUTEN-FREE DIET.

(Eng.) Heading, R. C.; Paterson, W. D.; McClelland, D. B. L.; Barnetson, R. S. C.; Murray, M. S. M. (Royal Infirmary, Edinburgh, Scotland). *Br. J. Dermatol.* 94(5):509-514; 1976.

The effect of a gluten-free diet (GFD) on the control of dermatitis herpetiformis-associated skin lesions was assessed prospectively for 2 yr in 26 patients on GFD and in 16 patients on a normal diet. Daily requirements for p.o. medication with sulfapyridine or dapsone were significantly reduced in patients on GFD, as compared to the statistically insignificant reduction observed in patients on a normal diet. If complete clinical remission occurred, it was maintained while the GFD was strictly observed; however, complete remission did not occur significantly more often in GFD-treated patients than in patients on a normal diet. GFD treatment seems desirable for the majority of patients with dermatitis herpetiformis, not only to correct the intestinal abnormality but also to minimize the dose of drugs necessary to control the skin lesions.

2257 PHASE II STUDY OF METHYL-CCNU (NSC-95441) IN ADVANCED GASTROINTESTINAL CANCER.

(Eng.) Engstrom, P. F.; Catalano, R. B.; Creech, R. H. (American Oncologic Hosp., Philadelphia, PA 19111). *Cancer Treat. Rep.* 60(3):285-287; 1976.

The effectiveness and toxicity of 1-(2-chloroethyl)-3-(4-methyl-cyclohexyl)-1-nitroso-urea (methyl-CCNU) were evaluated in 47 patients with advanced gastrointestinal adenocarcinoma. All patients received 200 mg/m^2 of body surface area methyl-CCNU p.o. after a 2-hr fast. Courses were repeated every 49 days until evidence of disease progression occurred. Complications included nausea (which could be ameliorated with chlorpromazine) and severe pancytopenia; the latter occurred in patients with extensive liver metastases or in those who had received previous radiotherapy or chemotherapy, and were thus given less than their predicted methyl-CCNU dosage. Although none of 26 patients with colorectal carcinoma showed complete or partial tumor regression, 5 experienced stabilization of the disease. Of 13 patients with metastatic gastric carcinoma, 1 had a 6-month complete regression of metastases. Measurable antitumor activity was seen in 2 of 11 patients with metastatic pancreatic carcinoma. Thirty-two patients showed no significant antitumor effect. The use of methyl-CCNU in combination with other active drugs in the treatment of gastrointestinal adenocarcinoma is being investigated.

2258 GASTRIN RESPONSE TO FOOD AFTER THREE TYPES OF INTESTINAL SHUNT OPERATIONS FOR OBESITY.

(Eng.) Dano, P.; Stadil, F. (Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):93-97; 1976.

LIBRARY U. S.

The basal and food-stimulated serum concentrations of gastrin and gastric secretion of acid were studied in 28 patients following 3 types of intestinal shunt operation for obesity. In each type, 48 cm of functioning small intestine was preserved, but the ratio between functioning jejunum and ileum was different (9 patients with proximal 36 cm of jejunum anastomosed to the distal 12 cm of ileum, 8 patients with anastomosis between 24 cm of proximal jejunum and 24 cm of terminal ileum, and 11 patients with the anastomosis between 12 cm of proximal jejunum and 36 cm of terminal ileum). The basal and stimulated concentrations of gastrin in serum were significantly higher in patients with the shortest jejunum in function. There was no difference in the gastric acid output. The results suggest that gastrin participates in evoking the gastric hypersecretion of acid following massive bowel resection or bypass. Deprivation of a hormonal inhibitory substance from the upper jejunum may be responsible for the increased serum gastrin concentration.

GENERAL

Parasitology

2284 IMMUNOLOGICAL STUDIES IN HUMAN SCHISTOSOMIASIS. I. PARASITIC ANTIGEN IN URINE. (Eng.) Carlier, Y.; Bout, D.; Bina, J. C.; Camus, D.; Figueiredo, J. F. M.; Capron, A. (Service d' Immunologie et de Biologie Parasitaire, U.E.R. de Medecine, Lille, France). *Am. J. Trop. Med. Hyg.* 24(6):949-954; 1975.

Circulating antigens were investigated by immunodiffusion in sera and urines from 132 patients with *Schistosoma mansoni* infections. The occurrence of a thermostable parasitic urinary antigen, called M, was demonstrated in 80% of infected patients. The incidence of M component was proportional to the fecal egg count and was inversely proportional to the age of the patient. Specific anti-M precipitating antibodies were demonstrated in 41% of sera from infected patients. A statistical correlation was found between the presence of M antigen and the level of total and anti-*S. mansoni* IgE, and also with the 24-hr intradermal test response with *S. mansoni* antigen. M antigen was not detected in serum. This may be due to the fact that sera were only concentrated 3-fold in these experiments, whereas the urines were concentrated at least 1,000-fold; alternatively, the M antigen may be complexed with specific antibodies in the serum.

See also, 1745, 1818, 1975.

2301 USE OF AN ELEMENTAL DIET FOR LONG-TERM NUTRITIONAL SUPPORT IN CROHN'S DISEASE. (Eng.) Goode, A.; Hawkins, T.; Feggetter, J. G. W.; Johnston, I. D. A. (Univ. Dept. Surgery, Newcastle Upon Tyne NE1 4LP, U.K.). *Lancet* 1(7951):122-124; 1976.

An elemental diet, consisting of amino acids with glucose, minerals, fat, and vitamins, was used for long-term (up to 360 days) nutritional support in eight patients with Crohn's disease. They had lost 30% (range 18-37%) of their weight while they were healthy. A whole-body monitor was used to measure total body potassium as an index of the lean tissue mass. Three preoperative patients who had been unable to maintain their weight on a normal diet were able to restore 10% per month of their lost lean tissue once they were established on an elemental diet. In five patients who had a successful resection of their bowel lesion, the postoperative rate of restoration of the lean tissue mass, while taking an elemental diet, was 18.5% per month, while in two control postoperative patients on a normal diet, it was 19% per month. The results indicate that elemental diets have a major therapeutic role in the arrest and reversal of chronic weight-loss.

2302 CROHN DISEASE AND PREGNANCY. (Eng.) Homan, W. P.; Thorbjarnarson, B. (New York Hosp.-Cornell Medical Center, 525 E. 68th St., New York, NY 10021). *Arch. Surg.* 111(5):545-547; 1976.

Seventy-eight married women of childbearing age (15-44 yr) with Crohn's disease were studied. Thirty-five patients had borne 50 children before the onset of their disease. There were 42 pregnancies in 26 women following the diagnosis of Crohn's disease, leaving 67% of the patients termed "subfertile" or "infertile." The site of the primary disease was not related to fertility. There were 31 pregnancies resulting in a living child. There were two elective abortions, one therapeutic abortion, seven spontaneous abortions, two cesarean sections, one stillbirth, one premature (<36 wk) birth, and 28 full-term vaginal deliveries. Thirty-two pregnancies occurred during a quiescent phase of the disease, and of these, a mild exacerbation during the pregnancy developed in three cases. Pregnancy occurred during the active phase of the disease in 10 patients. In 10 pregnancies (in eight patients), the postpartum course was characterized by exacerbation of the disease. It appears that the outcome of pregnancies in patients with Crohn's disease are statistically similar to that of the general population. Results indicate that pregnancy did not exert an adverse effect on the disease, itself, but termination of pregnancy was associated with relapse of Crohn's disease 24% of the time.
